intimation that they were *subscribed* by her. Whence arises this difference? From a *blunder* in the clerk penning the act of council, says one: From a habit contracted by the same clerk, which made him *mechanically* add *subscribed* to *written*, says another: From the *carelessness* of the writer who transcribed the copy of the act of council which has descended to us, says a third. These subtleties have been exposed in all their weakness by Messrs Tytler and Whitaker: but in this abstract it is sufficient to observe, that they are mere suppositions, supported by no evidence; and that the copy of the act of council which we have was given to the ministers of Elizabeth by the leaders of the faction, who were neither blundering clerks, nor under the habit of mechanically adding *subscribed* to *written*. Under one form, therefore, the letters were certainly exhibited before the council, and under another form they were produced in parliament; but had they been genuine, they would have appeared uniformly with the same face. The clerk of the council was Alexander Hay, a notary public accustomed to draw up writings and to attest them; and what puts his accuracy with respect to the letters beyond all possibility of doubt, his description of them is authenticated in the fullest manner by the signatures of Murray, Morton, and a long train of others who formed the secret council. The letters, therefore, were actually presented to the secret council with the customary appendage of subscription to them. But when these artificers of fraud came to reflect more closely on the approach of parliament, and to prepare their letters for the inspection of the friends of Mary, they began to shrink at the thoughts of what they had done. To substantiate the charge by letters under her own hand, they had naturally annexed her own subscription, a letter *unsubscribed* being a solecism in evidence. But most unfortunately for the cause of complete forgery, Mary was still in possession of her own seal, and he who fabricated the letters was not an engraver. For this reason, "the allegit writings in form of missive letters or epistles," says the bishop of Ross, in an address to Elizabeth, "are not *sellis* nor *signetis*." They were neither attested by her subscription at the bottom, nor secured by her seal on the outside. In the secret council, where all were equally embarked in rebellion, these omissions were of no importance. But that letters, containing intimations of adultery and of murder, should be sent by the queen to the earl of Bothwell, with her *subscription* to them, and yet without any guard of a seal upon them, so far exceeds all the bounds of credibility, that they could not expect it to gain the belief of parliament. They were struck with the absurdity of their plan, and dreaded a detection. They were under the necessity of altering it; but they could not supply the defect of the seal. They, therefore, wrote over the letters anew, and with-held the subscription.

These letters were now as complete as the conspirators wished them; yet in this state, while they were unsubscribed and unsealed, they wanted other formalities which are usual in dispatches. They were without directions, and they had no dates. They must, therefore, have been sent by the queen to Bothwell as *open and loose papers*; yet they contained evidence against

herself, and against him, of the most horrid wickedness; and Nicholas Hubert, the person who is said to have carried most of them, was of the lowest condition, and, as Dr Robertson characterizes him, "a foolish talkative fellow." He would, therefore, surely read those papers, which are polluted from end to end with open and uncovered adultery, and as surely report their contents to others. These are most incredible circumstances, on the supposition that the letters are authentic, unless the queen was, what none of her enemies ever represented her, an absolute idiot.

The letters in their composition bear no resemblance to the other writings of the queen. They have a vulgarity, an indelicacy, and a coarseness of expression and manner, that by no means apply to her. They breathe nothing of the passion of love besides the impulses of the sensual appetite; and they represent a queen highly accomplished in love with one of her subjects, as acting with all the sneaking humility of a cottager to a peer. A few instances will show this. "The devil find us," she is made to exclaim, "and God knit us togidder for ever for the maist faithful coupill that ever he unitit: *this is my feith; I will die in it.*" "I am," she says in another place, "varrey glad to wryte unto zow quhen the reit are sleipand; sen I cannot sleip as they do, and as I would desire, that is, in your armes, my dear lufe." "Seeing to obey zow, my dear lufe, I spare nauther honor, conscience, basarde, nor greates quabatymer; tak it, I pray zow, in gude part, as from the maist faithful luifer that ever ze had, or ever fall have." "Se not hir (his wife), quahis fenzeit teires suld not be sa mikle preist nor elemis as the trew and faithful trevellis quihik I susteine for to merite her place." "God give zow, my only lufe, the hap and prosperitie quihik your humble and faithful lufe desires unto zow, who *hopis* to be shortly another thing to you for the reward of my irkesome travells." "When I will put you out of dout, and cleir myselve, *refuse* it not, my dear lufe; and suffer me to make zow fume prufe be my obedience, my faithfulness, constancie, and voluntary *subjection*, quihik I tak for the plesandest gude that I might reseit, *gif ze will except it.*" "Such (says Mr Whitaker) was the coarse *kirtle*, and the homely *necktie*, in which these wretched representatives of Mary dressed themselves up, for the exhibition of a queen dignified, refined, and elegant—a queen whom, according to their own account, "God had indowit with mony gude and excellent gifts and virtues!"

The evidence which points to the forgery of the letters is profuse and instructive. In its separate parts, it is powerful and satisfactory. When taken together, and in the union of its parts, it is invincible. But, amidst all its cogency and strength, there is a circumstance most peculiarly in its favour, and of which it required no aid or assistance. By this peculiarity, it is cased completely in steel, and armed at every point. The letters have come down to us in the French, the Scottish, and the Latin languages. Now the conspirators affirmed, that they were written by the queen in the French language. But by a critical examination of them in these different languages, Mr Goodall demonstrated, that the pretended French originals are a translation from the Latin of Buchanan.

Mary.

Stewart.

Mary.

which is itself a version from the Scotch. This is indeed acknowledged by Dr Robertson, the ablest and most persevering of all Mary's enemies, who pretends, that, so far as he knows, it never was denied. Determined, however, to support the authenticity of the letters at all events, the same elegant and ingenious writer supposes †, that the French originals are now lost, but that two or three sentences of each of those originals were retained, and prefixed to the Scottish translation; and that the French editor observing this, foolishly concluded that the letters had been written partly in French and partly in Scottish. In support of this singular hypothesis, he proceeds to affirm, that "if we carefully consider those few French sentences of each letter which still remain, and apply to them that species of criticism by which Mr Goodall examined the whole, a clear proof will arise, that there was a French copy, not translated from the Latin, but which was itself the original from which both the Latin and Scottish have been translated." He accordingly applies this species of criticism, points out a few variations of meaning between what he calls the remaining sentences of the original French and the present Latin; and thinks, that in the former he has discovered a spirit and elegance which neither the Latin nor the Scottish have retained. His critical observations have been examined by Mr Whitaker; who makes it apparent as the noon-day sun, that the Doctor has occasionally mistaken the sense of the Latin, the French, and even the Scotch; and that he has *forgotten* to point out either the elegance or the spirit of any particular clauses in his pretended originals. The same masterly vindicator of Mary then turns his antagonist's artillery against himself; and demonstrates, that such variations as he has thought sufficient to prove the existence of a former French copy, are not confined to the first sentence of each of the three first letters, but are extended to other sentences, and diffused over all the letters. Hence he observes, that this mode of proving will demonstrate the *present* French, and *every* sentence in it, to be that very original, which it primarily pretended to be, which Mr Goodall has so powerfully proved it not to be, and which even the Doctor himself dares not assert it is. Our limits will not admit of our transcribing the observations of these two illustrious critics; nor is it necessary that we should transcribe them. By acknowledging that "Buchanan made his translation, not from the French but from the Scottish copy (of which he justly observes, that, were it necessary, several critical proofs might be brought)," Dr Robertson, in effect, gives up his cause. Had there been any other French letters than the present †, what occasion had Buchanan for the Scotch, when he himself must have had possession of the originals? It is evident from Mr Anderson's account, that those letters were translated by Buchanan at London during the time of the conferences. He was one of the assistants appointed to the rebel commissioners, and entrusted with the whole conduct of the process against the queen. By him, with Lethington, Macgill, and Wood, the original letters were exhibited, and their contents explained to the English commissioners; and we know from the authentic history of those papers, that they were neither lost nor mislaid for many years afterwards. It cannot be pre-

tended that Buchanan did not understand the French; for he past most of his life in that country, and taught a school there. He was, indeed, a daring zealot of rebellion; but, with all his audacity, he must have felt the task in which he was engaged a very ungracious one. When he sat down to defame, in the eyes of all Europe, a queen to whom he owed not only allegiance but also personal gratitude, it is not conceivable that he could have translated from a *Scotch translation*, had he known any thing of a *French original*; and if the rebel commissioners, who were said to produce them, knew nothing of such originals, certainly no body else ever did: if they existed not with Buchanan, they existed no where.

Dr Robertson, however, has another argument against Mr Goodall, which he thinks conclusive. Of the eight letters "the five remaining (he says) never appeared in Latin; nor is there any proof of their ever being translated into that language. Four of them, however, are published in French. This entirely overturns our author's hypothesis concerning the necessity of a translation into Latin."—An authentic fact will indeed overturn any hypothesis; but, most unluckily for this argument, the Doctor advances the hypothesis, and the fact rests with Mr Goodall. It is indeed true that Buchanan *published* only the three first letters in Latin at the end of his Detection; but it does not therefore follow, that the other five were never *translated into that language*. Indeed Mr Whitaker has made it as apparent as any thing can be, that the whole eight were turned into Latin for the use of the French translator, who, by his own account, understood not the Scotch. He has made it in the highest degree probable, that this translator was one *Gamus*, a French refugee; and he has demonstrated, that the translation was made in London under the eye of Buchanan himself. We do not quote his arguments, because they consist of a great number of observations which cannot be abridged; and because the translator himself confesses every thing which is of importance to the cause maintained by Mr Goodall. "Au reste (he tells us) *épistres mises sur la fin, which were all but the eighth, 'avaient été écrites par la Roynne, partie en François, partie en Ecossois; et depuis traductes ENTIEREMENT en LATIN: mais n'ayant cognoissance de la langue Ecossoise, j'ay mieux aimé exprimer tout ce, que j'ay trouve en LATIN, que,' &c.*" This confession (says Mr Whitaker) takes a comprehensive sweep. It makes all the seven letters at least, and the *whole* of each, to have been translated into Latin, and from thence to have been rendered into French. It starts no piddling objections about sentences or half-sentences, at the head or at the tail of any. It embraces all within its wide-spread arms. And it proves the fancied existence of a French copy at the time to be all a fairy vision; the creation of minds that have subjected their judgements to their imaginations; the invited dreams of self-delusion."

The letters, so weak on every side, and so incapable of sustaining any scrutiny, give the marks of suspicion and guilt in all the stages of their progress. Even with the parliamentary sanction afforded to them by the three estates, which the earl of Murray assembled upon the 15th day of December 1567, he felt the

Mary.

Dissert.

† Tylor's Inquiry.

Mary. delicacy and the danger of employing them *openly* to the purposes for which they were invented. For while he was scheming with Elizabeth his accusation of the queen of Scots, he took the precaution to submit privately the letters to that princess by the agency of his secretary Mr Wood. The object of this secret transaction, which took place early in the month of June 1568, was most flagitious, and presses not only against the integrity of Murray, but also against that of the English queen. Before he would advance with his charge, he solicited from her an assurance that the judges to be appointed in the trial of Mary would hold the letters to be true and probative.

§ Stuart.

By the encouragement of Elizabeth, the earl of Murray was prevailed upon to prefer his accusation §. He was soon to depart for England upon this business. A privy-council was held by him at Edinburgh. He took up in it with formality the letters of the queen from the earl of Morton, and gave a receipt for them to that nobleman. That receipt is remarkable and interesting. It is dated upon the 16th day of September 1568, and contains the first mention that appears in history of the discovery of the letters as in the actual possession of Dalgleish upon the 20th of June 1567. This, as we have already noticed, is a very suspicious circumstance; but it is not the only suspicious circumstance which is recorded in the receipt. In the act of secret-council, and in the ordination of parliament, in December 1567, when the earl of Murray and his associates were infinitely anxious to establish the criminality of the queen, the only vouchers of her guilt to which they appealed were the letters; and at that time, doubtless, they had prepared no other papers to which they could allude. But in Murray's receipt in September 1568, there is mention of other vouchers beside the letters. He acknowledges, that he also received from the earl of Morton contracts or obligations, and sonnets or love-verses. These remarkable papers, though said to have been found upon the 20th of June 1567, appeared not till September 1568; and this difficulty is yet to be solved by those who conceive them to be genuine. The general arguments which affect the authenticity of the letters apply to them in full force; only it must be observed, that as the original letters were undoubtedly in Scotch, the original sonnets were as certainly written in French. This has been completely proved by Dr Robertson, and is fully admitted by Mr Whitaker, who has made it in the highest degree probable that Lethington forged the letters and Buchanan the sonnets. Be this as it may, the sonnets have every external and internal evidence of forgery in common with the letters, and they have some marks of this kind peculiar to themselves. In particular, they make the love of Mary still more grovelling than the letters made it; and with a degree of meanness, of which the soul of Lethington was probably incapable, the author of the sonnets has made the queen consider it as "na lytill honor to be maistress of her subject's guds!" In this the dignified princess is totally lost in "the maid Marien" of her pretended imitators; and Buchanan, who in his commerce with the sex was a mere sensualist, forgot on this occasion that he was personating a lady and a queen.

There is, however, in these sonnets, one passage of

singular importance, which we must not pass wholly unnoticed. The queen is made to say,

*Pour luy aussi j'ay jetté mainte larme,
Premier qu'il fust de ce corps possesseur,
Duquel alors il n'avoit pas le cœur.
Puis me donna un autre dur alarme,
Quand il versa de son sang mainte drague.*

For him also I powrit out my teyris,
First quhen he made himself possessor of this body,
Of the quhill then he had not the hart.
Efter he did give me ane uther hard charge,
Quhen he bled of his blude greit quantitie, &c.

If these sonnets could be supposed to be genuine, this passage would overthrow at once all the letters and both the contracts which were produced; and would prove, with the force of demonstration, that the seizure of Mary by Bothwell was *not* with her own consent; that he actually committed a *rape* upon her; that she had for him *no love*; and that the married him merely as a *refuge* to her *injured honour*. The sonnets, however, are undoubtedly spurious; but, considered in this light, the verses before us prove with equal force the full conviction in the minds of the rebels of what in an unguarded moment they actually confessed to Throgmorton, and was manifest to all the world: viz. that "the queen their sovereign was *led captive*, and by *fear, force*, and (as by many conjectures may be well suspected) other *extraordinary* and more *unlawful* means compelled to become bed-fellow to another wife's husband." They prove likewise, that after the rape, finding Mary highly indignant at the brutality done her, Bothwell actually flabbed himself; not, we may believe, with any intention to take away his own life, but merely that by shedding many a "drachm" of blood he might mollify the heart of the queen.

But we mean not to pursue the history of the sonnets any farther. Though they were undoubtedly invented in aid of the letters, to prove that fundamental principle of the conspirators,—that the love of Mary to Bothwell was inordinate; yet they are so incompatible with history, and with one another, that they demonstrate the spurioufness of themselves, and of the evidence which they were intended to corroborate. By thus endeavouring to give an air of nature and probability to their monstrous fictions, the rebels at once betrayed the fabrication of the whole. They have themselves supplied us with a long and particular journal, to show the true dates of facts; and by that journal have their letters and their sonnets been demonstrated to be spurious. "The makers of these papers (says Mr Whitaker) have broken through all the barriers of their own history. They have started aside from the orbit of their own chronology. They have taken a flight beyond the bounds of their own creation, and have there placed themselves conspicuous in the PARADISE OF FOOLS."

This mass of forgery was clandestinely shown to Elizabeth's commissioners during the conferences at York: (See SCOTLAND.) It was shown again to the same commissioners and others during the conferences at Westminster. But neither Mary nor her commissioners could ever procure a sight of a single letter or a single sonnet. By the bishop of Ross and the Lord Herties.

Mary. Herries she repeatedly demanded to see the papers said to be written by her; but that request, in itself so reasonable, Elizabeth, with an audacity of injustice of which the history of mankind can hardly furnish a parallel, thought fit to refuse. Mary then instructed her commissioners to demand copies of the letters and sonnets; and offered even from these to demonstrate in the presence of the English queen and parliament, and the ambassadors of foreign princes, that the pretended originals were palpable forgeries. Even this demand was denied her; and there is undoubted evidence still existing, that neither the nor her commissioners had so much as a copy of these criminal papers till after those important conferences had for some time been at an end. This last demand perplexed Elizabeth; the conferences were suddenly broken up; Murray was dismissed with his box to Scotland; and the letters were seen no more!

But the letters, we are told, were at Westminster compared with letters of the queen's, and found to be in the same Roman hand. They were indeed compared with other writings; but with what writings? This question let Elizabeth's commissioners themselves answer. They collated them, they say "with others her letters, which were shewed yesternight, and avowed by THEM (the rebel commissioners) to be written by the said queen." This was such a collation as

Whitaker must have pronounced them to be idiots &c, if we had not known them to be otherwise; and such as must pronounce them to be knaves, as we know them to have been men of sense. Like persons totally incompetent to the management of business, but in truth acting ministerially in the work of profligacy, they compared the letters produced, not with letters furnished by Mary's commissioners, not with letters furnished even by indifferent persons, but with letters *presented by the producers themselves*.—"This (says Mr Whitaker) is such an instance of imposition upon Mary and the world, as can scarcely be paralleled in the annals of knavery. Many instances of imposition, indeed, occur in the wretched history of our race; but we can hardly find one, in which the imposition was so gross, so formal, so important, and so clear. It was very gross, because it has not a shred of artifice to cover its ugly nakedness. It was very formal, because it was done by men some of whom were of the first character in their country; and all were bound by honour, and tied down by oaths, to act uprightly in the business. It was very important, because no less than the reputation of a queen, and the continuance of an usurpation, depended upon it. And it is very clear, because we have the fact related to us by

the commissioners themselves, recorded to their shame in their own journal, and transmitted by their own hands to posterity with everlasting infamy on their heads."

When Tytler's *Inquiry into the Evidence produced by the Earls of Murray and Morton against Mary Queen of Scots* was first published, it was reviewed in the Gentleman's Magazine by the late Dr Johnson. The review, which consists of a brief analysis of the work, with reflections interspersed on the force of the evidence, concludes thus:—"That the letters were forged is now made so probable, that perhaps they will never more be cited as testimonies." Subsequent experience has shown, that the great critic's knowledge of human nature had not deserted him when he guarded his prediction with the word *perhaps*. Few authors possess the magnanimity of Fenelon; and it is not to be expected that he who has once maintained the letters to be genuine, should by reasoning or criticism be compelled to relinquish them: but we are persuaded, that, after the present generation of writers shall be extinct, these letters and sonnets will never be cited as evidence, except of the profligacy of those by whom they were fabricated. Having said this, we leave the general character of Mary to the reflection of the reader (A).

She wrote, 1. Poems on various occasions, in the Latin, French, and Scotch languages. One of her poems is printed among those of A. Blackwood; another in Brantome's *Dames illustres*, written on the death of her first husband Francis. 2. Consolation of her long imprisonment, and royal advice to her son. 3. A copy of verses, in French, sent with a diamond-ring to queen Elizabeth. There is a translation of these verses among the Latin poems of Sir Thomas Chaloner. 4. Genuine Letters of Mary queen of Scots, to James earl of Bothwell; translated from the French, by E. Simmonds, 1726. There are, besides, many other of her epistles to queen Elizabeth, secretary Cecil, Mildmaye, &c. which are preserved in the Cottonian, Ashmolean, and other libraries.

MARY II. queen of England, eldest daughter of James II. by his first wife, was born at St James's in 1662. She was bred up a Protestant, and married to William Henry of Nassau, then prince of Orange, afterward king of England, in the 16th year of her age. She staid in Holland with her husband till February 12. 1689, when she came over, and was solemnly proclaimed queen of England, &c. She was an equal sharer with her husband in all the rights belonging to the crown; but the administration and execution thereof was lodged solely in the king. She was a princess endowed with the highest

(A) This article stands in need of an apology; but whether for its length or its shortness, our readers may perhaps differ in opinion. If it be considered as a piece of common biography, and compared with the limits which we have prescribed to our other articles of the same kind, it has swelled to an extent beyond all proportion. But as a piece of common biography it ought not to be considered: it is intimately connected with the history of Scotland at a very interesting period; and it has been justly observed, by one of the ablest writers of the age, that "the fact under dispute in the life of Mary, is a fundamental and essential one; and that, according to the opinion which the historian adopts with regard to it, he must vary and dispose the whole of his subsequent narration." Viewed in this light, our abstract of the evidence which has been urged on both sides of this controversy will by many be deemed too short. To such as wish for complete satisfaction, we can only recommend the unbiassed study of the writings of Buchanan, Leslie bishop of Ross, Goodall, Robertson, Hume, Tytler, Sir David Dalrymple, Stuart, and Whitaker.

Mary
Maryland.

est perfections both of body and mind : she loved history, as being proper to give her useful instructions ; and was also a good judge as well as a lover of poetry. She studied more than could be imagined, and would have read more than she did if the frequent returns of ill-humours in her eyes had not forced her to spare them. She gave her minutes of leisure to architecture and gardening ; and since it employed many hands, she said she hoped it would be forgiven her. She was the most gracious of sovereigns to her subjects, and the most obliging of wives to her husband, as well as the most excellent of mistresses to her servants : she ordered good books to be laid in the places of attendance, that persons might not be idle while they were in their turns of service. She was exceeding zealous for a reformation of manners ; charitable in the highest degree, without the least ostentation. This excellent queen died on the 28th of December 1695, at Kensington, of the small-pox, in the 33d year of her age. In her the arts lost a protectress, the unfortunate a mother, and the world a pattern of every virtue. As to her person, she was tall, of a majestic graceful mien, her countenance serene, her complexion ruddy, and her features beautiful.

MARY MAGDALEN'S DAY, a festival of the Romish church, observed on the 22d of July.

MARY-GERANE'S HOUSE, a name given to Dunmorehead, in the parish of Dunneen, county of Kerry, and province of Munster, in Ireland. It is the most western point of all Europe, and called by the Irish *Ty Vorney Geerone*. It is a point as much celebrated by them as John-of-Groat's-house by the Scots, which is the utmost extremity of North Britain.

MARYBOROUGH, a borough, market, and post town, and the assizes town to the Queen's county, in the province of Leinster, in Ireland, so called in honour of Mary queen of England, who reduced this part of the country to three-gird by act of parliament 6th and 7th Philip and Mary. It is governed by a burgo-master and bailiffs, and has a barrack for a troop of horse. It returns two members to parliament, and has five fairs. It is distant from Dublin 40 miles. N. Lat. 53. 0. W. Long. 7. 20.

MARYBURGH. See *FORT-WILLIAM*.

MARYGOLD. See *CALTHA*.

Corn MARYGOLD. See *CHRYSANTHEMUM*.

French MARYGOLD. See *TAIGETES*.

MARYLAND, one of the Thirteen United States of America. It received that name in honour of Henrietta Maria, the consort of king Charles I. who made a grant of this country, with very extraordinary powers, to Lord Baltimore. It lies between 38 and 40 degrees north latitude, and in longitude from 74 to 78 degrees west from London. It is bounded on the north by Pennsylvania ; on the east by the Delaware state ; on the south-east and south by the Atlantic Ocean, and a line drawn from the ocean over the peninsula (dividing it from Accomack county in Virginia) to the mouth of Patomack river, thence up the Patomack to its first fountain, thence by a due north line till it intersects the southern boundary of Pennsylvania, in lat. 39° 43' 18" ; so that it has Virginia on the south, south-west, and west. It contains about 14,000 square miles, of which about one-sixth is water. It is divided into 18 counties, 10 of which are on the

western and 8 on the eastern shore of Chesapeake bay, St Mary's, Somerset, Calvert, Montgomery, Washington, Queen Ann's, Caroline, Kent, Charles, Talbot, Dorchester, Baltimore, Ann Arundel, Worcester, Harford, Cecil, Frederick, and Prince George's. Each of the counties sends four representatives to the house of delegates ; besides which the city of Annapolis and town of Baltimore send each two, making in the whole 76 members. The climate is generally mild and agreeable, suited to agricultural productions and a great variety of fruit-trees. In the interior hilly country the inhabitants are healthy ; but in the flat country, in the neighbourhood of the marshes and stagnant waters, they are, as in the other southern states, subject to intermittents. Chesapeake bay divides this state into the eastern and western divisions. It affords several good fisheries ; and, in a commercial view, is of immense advantage to the state. It receives a number of the largest rivers in the United States. From the eastern shore in Maryland, among other smaller ones, it receives Pokomoke, Choptank, Chester, and Elk rivers ; from the north the rapid Susquehannah ; and from the west Patapsco, Severn, Patuxent, and Patomack, half of which is in Maryland and half in Virginia. Except the Susquehannah and Patomack, these are small rivers. East of the blue ridge of mountains, which stretches across the western part of this state, the land, like that in all the southern states, is generally level and free of stones. Wheat and tobacco are the staple commodities of Maryland. In the interior country, on the uplands, considerable quantities of hemp and flax are raised.

The number of inhabitants in this state, including the negroes, is 254,050 ; which is 18 for every square mile. The inhabitants, except in the populous towns, live on their plantations, often several miles distant from each other. To an inhabitant of the middle, and especially of the eastern states, which are thickly populated, they appear to live very retired and unsocial lives. The effects of this comparative solitude are visible in the countenances as well as in the manners and dress of the country people ; there being among them very little of that cheerful sprightliness of look and action which is the invariable and genuine offspring of social intercourse ; nor do they pay that attention to dress which is common, and which decency and propriety have rendered necessary, among people who are liable to receive company almost every day. As the negroes perform all the manual labour, their masters are left to saunter away life in sloth, and too often in ignorance. These observations, however, must in justice be limited to the people in the country, and to those particularly whose poverty or parsimony prevents their spending a part of their time in populous towns, or otherwise mingling with the world.

The chief towns in this state are Annapolis and Baltimore.—*Annapolis*, the capital, and the wealthiest town of its size in America, is situated just at the mouth of Severn river, 30 miles south of Baltimore. The houses are generally large and elegant ; and the state-house is the noblest building of the kind in America.—*Baltimore* has had the most rapid growth of any town on the continent, and is the fourth in size and the fifth in trade in the United States. It lies in lat. 39. 21. on the north side of Patapsco river.

Maryland.

Maryland. around what is called the *Bafon*. The situation of the town is low. The houses were numbered in 1787, and found to be 1955; about 1200 of which were in the town and the rest at Fell's point. The number of stores was 152; and of churches 9, which belong to German Calvinists and Lutherans, Episcopalians, Presbyterians, Roman Catholics, Baptists, Methodists, Quakers, Nicolites, or New Quakers. The number of inhabitants is between 10,000 and 11,000. There are many very respectable families in Baltimore, who live genteelly, are hospitable to strangers, and maintain a friendly and improving intercourse with each other; but the bulk of the inhabitants, recently collected from almost all quarters of the world, bent on the pursuit of wealth, varying in their habits, their manners, and their religions, if they have any, are unfocial, unimproved, and inhospitable. The trade of Maryland is principally carried on from Baltimore, with the other states, with the West Indies, and with some parts of Europe. To these places they send annually about 30,000 hogheads of tobacco, besides large quantities of wheat, flour, pig iron, lumber, and corn—beans, pork, and flax-seed, in smaller quantities; and receive in return, clothing for themselves and negroes, and other dry goods, wines, spirits, sugars, and other West India commodities. The balance is generally in their favour.

The Roman Catholics, who were the first settlers in Maryland, are the most numerous religious sect. Besides these, there are Protestant Episcopalians, English, Scots, and Irish Presbyterians, German Calvinists, German Lutherans, Friends, Baptists, Methodists, and Nicolites, or New Quakers. The colleges in this state have all been founded since the year 1782, and are yet in their infancy. The names of the several seminaries are, Washington College at Cheltenham, instituted in 1782; St John's College at Annapolis, founded in 1784; Cakesbury College at Abingdon, instituted by the Methodists in 1785; and a college founded by the Roman Catholics at Georgetown. There are a few other literary institutions, of inferior note, in different parts of the state, and provision is made for free schools in most of the counties: though some are entirely neglected, and very few carried on with any success; so that a great proportion of the lower class of people are ignorant, and there are not a few who cannot write their names. But the revolution, among other happy effects, has roused the spirit of education, which is fast spreading its salutary influences over this and the other southern states.

The legislature of this state is composed of two distinct branches, a senate and house of delegates; and styled *The General Assembly of Maryland*. The senate consists of 15 members, chosen every five years. Nine of these must be residents on the western shore and six on the eastern; they must be more than 25 years of age, must have resided in the state more than three years next preceding the election, and have real and personal property above the value of £.1000. The house of delegates is composed of four members for each county, chosen annually on the first Monday in October. The city of Annapolis and town of Baltimore send each two delegates. The qualifications of a delegate are, full age, one year's residence in the

county where he is chosen, and real or personal property above the value of £.500. The qualifications of a freeman are, full age, a freehold estate of 50 acres of land, and actual residence in the county where he offers to vote; property to the value of £.30 in any part of the state, and a year's residence in the county where he offers to vote.

On the second Monday in November annually a governor is appointed by the joint ballot of both houses. The governor cannot continue in office longer than three years successively, nor be elected until the expiration of four years after he has been out of office. The qualifications for the chief magistracy are, 25 years of age, five years residence in the state next preceding the election, and real and personal estate above the value of £.5000, £.1000 of which must be freehold estate. This constitution was established by a convention of delegates at Annapolis, August 14. 1776.

Maryland was granted, as has been already noticed, by King Charles I. to Cecilius Calvert, baron of Baltimore in Ireland, June 20. 1632. The government of the province was by charter vested in the proprietary; but it appears that he either never exercised these powers alone, or but for a short time. The honourable Leonard Calvert, Esq; Lord Baltimore's brother, was the first governor or lieutenant-general. In 1638, a law was passed, constituting the first regular house of assembly, which was to consist of such representatives, called *burgesses*, as should be elected pursuant to writs issued by the governor. These burgesses possessed all the powers of the persons electing them; but by any other freemen, who did not assent to the election, might take their seats in person. Twelve burgesses or freemen, with the lieutenant-general and secretary, constituted the assembly or legislature. This assembly sat at St Mary's, one of the southern counties, which was the first settled part of Maryland. In 1689, the government was taken out of the hands of Lord Baltimore by the grand convention of England. Mr Copley was appointed governor by commission from William and Mary in 1692, when the Protestant religion was established by law. In 1716, the government of this province was restored to the proprietary, and continued in his hands till the late revolution; when, being an absentee, his property in the lands was confiscated, and the government assumed by the freemen of the province, who formed the constitution now existing. At the close of the war, Henry Harford, Esq; the natural son and heir of Lord Baltimore, petitioned the legislature of Maryland for his estate; but his petition was not granted. Mr Harford estimated his loss of quit-rents, valued at 20 years purchase, and including arrears, at £.259,488, 5s.—dollars at 7s. 6d. and the value of his manors and reserved lands at £.327,441 of the same money.

MARYPORT, a sea-port town of Cumberland, situated at the mouth of the Elne. It has a good harbour; and has 70 or 80 sail of shipping from 30 to 250 tons burden, principally employed in the coal-trade; some of them fail up the Baltic for timber, flax, iron, &c. They have a furnace for cast-iron and a glass-house. A chapel was erected here in 1760.

MAS (Lewis du), natural son to Jean Louis de Montcalm.

Maryland
||
Mas.

—Mas,
Masluero.

Montcalm Seigneur de Candiac, and a widow of rank of Rouergue, was born at Nîmes in 1676. His first attention was bestowed on jurisprudence; but afterwards he was altogether occupied with mathematics, philosophy, and the study of the languages. Father Mallebranche cultivated his acquaintance and esteemed his virtues. His first appearance was severe, his general temper tranquil; yet he had a lively and fertile imagination. His mind was active, full of resources, and methodical. We are indebted to his industry for the Typographical Bureau. This invention is the more ingenious, as it presents the tedious parts of education, namely, reading, writing, and the elements of languages, to the youthful mind as a delightful entertainment, and many people in France both in the capital and in the provinces have adopted it with success. After he had conceived the idea of this invention, he made the first trial of it on the young Candiac, who was remarkable for his understanding in his earliest years. Du Mas conducted his pupil to Paris and the principal cities in France, where he was universally admired. This prodigy was carried off in the year 1726 before he was seven years of age, and his loss had nearly deprived Du Mas of his reason. A dangerous illness was the consequence of his vexation; and he would have died of want, if a gentleman had not taken him from his garret and entertained him in his own house. Du Mas afterwards retired with Madame de Vaujour within two leagues of Paris, and died in the year 1774, aged 68. He was a philosopher both in genius and character. His works are, 1. *L'Art de transporter toutes sortes de Musiques sans être obligé de connoître, ni le temps, ni le mode*, published at Paris in 4to, 1711. This work is extremely curious, but of no advantage to the study of music. 2. A volume in quarto, printed at Paris 1733, in four parts, intitled, *Bibliothèque des enfans*. In this treatise he has placed, in a clear point of view, the system and economy of his Typographical Bureau. This invention, like every thing new, was censured by some and admired by others. The author himself defended it with much success in the journals and in several occasional pamphlets. This collection, however, is become exceedingly scarce. The Typographical Bureau was brought to perfection by M. Reybert a citizen of Avignon, who enriched it with many articles containing useful and agreeable information in geography, history, fable, &c. &c. 3. *Mémoires de l'Ecluse sous le regne de Marie Stuart*, by Crawford, and translated from the English. This translation was found in manuscript in the library of the late marquis d'Aubais, with whom du Mas had lived in the most intimate habits of friendship.

Mas Planta, a plant which upon the same root produces male flowers only. See *MASCULUS Flor.*

MASAFUERO, an island of the South-Sea, lying in S. Lat. 33. 45. W. Long. 80. 46. It is very high and mountainous, and at a distance seems to consist of one hill or rock. It is of a triangular form, and seven or eight leagues in circumference. There is such plenty of fish, that a boat with a few hooks and lines may very soon catch as many as will serve 100 people. Here are coal-fish, cavilliers, cod, halibut, and cray-fish. Captain Carteret's crew caught a kingfisher that weighed 87 pounds, and was five feet and

an half long. The sharks were here so ravenous, that, in taking soundings, one of them swallowed the lead, by which they hauled him above water; but he regained his liberty by disgorging his prey. Seals are so numerous here, that Captain Carteret says, if many thousands were killed in a night, they would not be missed next morning. These animals yield excellent train-oil; and their hearts and plucks are very good food, having a taste something like those of a hog; their skins are covered with a very fine fur. There are many birds here, and some very large hawks. Of the pintado bird one ship caught 700 in one night. Commodore Byron landed here with difficulty in 1765, in order to take in wood and water, of both which he found plenty. He found also great numbers of goats, whose flesh tasted as well as venison in England.

MASBOTHÆI, or MESBOTHÆI, the name of a sect, or rather of two sects; for Eusebius, or rather Hegesippus whom he cites, makes mention of two different sects of Masbothæans. The first was one of the seven sects that arose out of Judaism, and proved very troublesome to the church; the other was one of the seven Jewish sects before the coming of Jesus Christ.

The word is derived from the Hebrew שבת, *schabat*, "to rest or repose," and signifies *idle easily indolent people*. Eusebius speaks of them as if they had been so called from one Masbothæus their chief: but it is much more probable that their name is Hebrew, or at least Chaldaic, signifying the same thing with a Sabbatarian in our language; that is, one who makes profession of keeping Sabbath.

Valeius will not allow the two sects to be confounded together: the last being a sect of Jews before, or at least contemporary with Christ; and the former a sect of heretics descended from them. Rufinus distinguishes them in their names: the Jewish sect he calls Masbuthæi; and the heretics Masbuthæani. The Masbuthæans were a branch of the Simonians.

MASCARDI (Augustin), a distinguished person in the republic of letters, was born at Sarzane, a city of the state of Genoa, in 1591. He spent the early part of his life among the Jesuits, and afterwards became chamberlain to Pope Urban VIII. He was naturally so eloquent, that this same pope, merely to exercise his talent, founded a professorship of rhetoric for him in the college de la Sapienza 1628, and settled upon him for life a pension of 500 crowns. Mascardi filled the chair with great reputation; but his love of letters made him neglect what is of more consequence than even letters, the management of his affairs: for he was always poor, and always in debt. He wrote a great many things in verse and prose; and among the rest, a treatise intitled *Dell' arte historica*. In his "History of the Conspiracy of the Comtede Fiesque," he has very frequently attacked the religion of Hubert Folietta; and in his other books he used some writers in the same way, which occasioned him to be attacked in his turn. The objections which were made to him, together with his answers, were added to the second edition of the history just mentioned. He died at Sarzane, 1640, in his 49th year.

MASCARON (Julius), bishop of Agen, and a most eminent French preacher, was born at Marcellis in

Masbothæi
Masfaron.

*Masclaf,
Masculine*

in 1634. He inherited of his father, who was the most celebrated advocate of the parliament of Aix, that uncommon talent of eloquence which distinguished him. He was admitted a member of the congregation of the oratory very young; and from his 22d year taught rhetoric at Mans. Soon after this he commenced preacher, and preached with great success in St Peter's church at Saumur. The bishop of Mans, willing to engage so able a preacher in his church, made him prebendary of it. He was much admired at Paris, when he preached the advent at the oratory. He preached after this five or six years at court, and was promoted to the bishopric of Tulle in 1671. He was afterwards translated to the bishopric of Agen. He was called in 1694 to preach the Lent sermon at court. The year following, he opened the assembly of the clergy, and returned to his diocese; where he died of a dropy in his chest, Dec. 16. 1703. There is nothing printed of this great man excepting A Collection of Funeral Orations made upon the queen-mother, the dauphiness, the duke of Beaufort, the chancellor Seguier, marshal Turenne; and at the head of this collection there is a short life of him.

MASCLEF (Francis), was at first a curate in the diocese of Amiens, the place of his birth, and afterwards theologian and confidant to the virtuous De Brou bishop of that diocese. He was appointed to the charge of a seminary of learning under that prelate. He deserved this employment both from his piety and profound learning. The oriental languages were as familiar to him as his native tongue. He pursued his researches into the idioms of the east with the spirit and the ingenuity of a philosopher. He was made canon of Amiens a little before the death of De Brou, which happened in 1706. His opinions on the Janesist controversy were so offensive to Sabbatier, the successor of that worthy prelate, that he was removed from the care of the seminary and from almost every other public office which he held. The regard of the dead comforted Masclaf under the oppression of the living. He devoted himself to study with so much ardour, that he contracted a disease of which he died the 14th Nov. 1728, aged 66 years. His principal works are, 1. A Hebrew Grammar in Latin, after his new method, printed at Paris 1716, in 12mo. This grammar was again printed in two volumes in 12mo in the year 1730, under the direction of M. de la Bletterie at that time priest of the oratory and the friend of Masclaf. All the objections which Father Guarin made in his Hebrew grammar to Masclaf's method of reading Hebrew without the use of points are attended to in this edition. There is nothing more necessary, according to this plan, than to take the vowel which is next the consonant in the order of the alphabet. This method was approved of by some learned men, but rejected by a great many more. 2. *Les Conférences Ecclésiastiques du diocèse d'Amiens*, in 12mo. 3. *Le Catéchisme d'Amiens*, in 4to. 4. *Une Philosophie et une Théologie*, in MS. These would have been published had they not discovered a partiality to the principles of Janesism. The author was an austere man, equally respectable for his manners and his knowledge.

MASCULINE, something belonging to the male, or the stronger of the two sexes. See MALE.

Vol. X. Part II.

MASCULINE, is more ordinarily used in grammar to signify the first and worthiest of the genders of nouns. See GENDER.

The masculine gender is that which belongs to the male kind, or something analogous to it.

Most substances are ranged under the heads of masculine or feminine.—This, in some cases, is done with a show of reason; but in others is merely arbitrary, and for that reason is found to vary according to the languages and even according to the words introduced from one language into another.—Thus the names of trees are generally feminine in Latin and masculine in the French.

Farther, the genders of the same word are sometimes varied in the same language. Thus *aloué*, according to Priscian, was anciently masculine, but is now become feminine. And *navire*, “a ship,” in French, was anciently feminine, but is now masculine.

MASCULINE RHYME, in the French poetry, is that made with a word which has a strong, open, and accented pronunciation; as all words have, excepting those which have an *e* feminine in their last syllable. For instance, *amour* and *jour*, *mort* and *fort*, are masculine rhymes; and *pere* and *mere*, *gloire* and *memoire*, are feminine. Hence also verses ending with a masculine rhyme, are called *masculine verses*, and those ending with a feminine rhyme, *feminine verses*. It is now a rule established among the French poets never to use the above two masculine or two feminine verses successively, except in the looser kind of poetry. Marot was the first who introduced this mixture of masculine and feminine verses, and Ronsard was the first who practised it with success. The masculine verses should always have a syllable less than the feminine ones.

MASCULINE SIGNS. Astrologers divide the signs into masculine and feminine; by reason of their qualities, which are either active, and hot or cold, accounted masculine; or passive, dry and moist, which are feminine. On this principle they call the Sun, Jupiter, Saturn, and Mars, *masculine*; and the Moon and Venus *feminine*. Mercury, they suppose, partakes of the two. Among the signs, Aries, Libra, Gemini, Leo, Sagittarius, Aquarius, are masculine: Cancer, Capricornus, Taurus, Virgo, Scorpio, and Pisces, are feminine.

MASCULUS FLOS, in botany. See FLOS.

MASH, a drink given to a horse, made of half a peck of ground malt put into a pail, into which as much scalding hot water is poured as will wet it very well: when that is done, stir it about, till, by tasting, you find it as sweet as honey; and when it has stood till it is lukewarm, it is to be given to the horse. This liquor is only used after a purge, to make it work the better; or after hard labour, or instead of drink in the time of any great sickness.

MASK. See MASQUE.

MASINISSA, a king of a small part of Africa, who at first assisted the Carthaginians in their wars against Rome; but afterwards joined the Romans, and became the firmest ally they ever had. See NUMIDIA.

MASON, a person employed under the direction of an architect, in the raising of a stone-building.

*Masculine
Mason,*

The chief business of a mason is to make the mortar; raise the walls from the foundation to the top, with the necessary retreats and perpendiculars; to form the vaults, and employ the stones as delivered to him. When the stones are large, the business of hewing or cutting them belongs to the stone-cutters, though these are frequently confounded with masons: the ornaments of sculpture are performed by carvers in stones or sculptors. The tools or implements principally used by them are the square, level, plumb-line, bevel, compass, hammer, chisel, mallet, saw, trowel, &c. See SQUARE, &c.

Besides the common instruments used in the hand, they have likewise machines for raising of great burdens, and the conducting of large stones; the principal of which are the lever, pulley, wheel, crane, &c. See LEVER, &c.

Free and Accepted MASONS, a very ancient society or body of men: so called, either from some extraordinary knowledge of masonry or building, which they are supposed to be masters of, or because the first founders of the society were persons of that profession. These are now very considerable, both for number and character, being found in every country in Europe, and consisting principally of persons of merit and consideration. As to antiquity, they lay claim to a standing of some thousand years. What the end of their institution is, seems still in some measure a secret; and they are said to be admitted into the fraternity by being put in possession of a great number of secrets, called the *mason's word*, which have been religiously kept from age to age, being never divulged. * See *Free-Masonry*.

MASONRY, in general, a branch of architecture, consisting in the art of hewing or squaring stones, and cutting them level or perpendicular, for the uses of building: but, in a more limited sense, masonry is the art of assembling and joining stones together with mortar.

Hence arise as many different kinds of masonry as there are different forms and manners for laying or joining stones. Vitruvius mentions several kinds of masonry used among the ancients: three of hewed stone, viz. that in form of a net, that in binding, and that called the *Greek masonry*; and three of unhewed stones, viz. that of an equal course, that of an unequal course, and that filled up in the middle; and the seventh was a composition of all the rest.

Net-masonry, called by Vitruvius *reticulatum*, from its resemblance to the meshes of a net, consists of stones squared in their courses, and so disposed as that their joints go obliquely; and their diagonals are the one perpendicular and the other level. This is the most agreeable masonry to the eye, but it is very apt to crack. See N^o 1.

Bound-masonry, that in which the stones were placed one over another, like tiles; the joints of their beds being level, and the mounters perpendiculars, so that the joint that mounts and separates two stones always falls directly over the middle of the stone below. This is less beautiful than the net-work; but it is more solid and durable. See N^o 2.

Greek masonry, according to Vitruvius, is that where after we have laid two stones, each of which makes a course, another is laid at the end, which makes two

courses, and the same order is observed throughout the building; this may be called *double-binding*, in regard the binding is not only of stones of the same course with one another, but likewise of one course with another course. See N^o 3.

Masonry by equal courses, called by the ancients *isodomum*, differs in nothing from the bound masonry, but only in this, that its stones are not hewn. See N^o 4.

Masonry by unequal courses, called *pseudisodomum*, is also made of unhewed stones, and laid in bound work; but then they are not of the same thickness, nor is there any equality observed excepting in the several courses, the courses themselves being unequal to each other. See N^o 5.

Masonry filled up in the middle, is likewise made of unhewed stones, and by courses; but the stones are only set in order as to the courses: (See N^o 9). A, the courses; B, the parts filled up; C, a coat of plaster.

Compound masonry is of Vitruvius's proposing, so called as being formed of all the rest. In this the courses are of hewed stone; and the middle being left void, is filled up with mortar and pebbles thrown in together: after this the stones of one course are bound to those of another course with iron-cramps fastened with melted lead: (See N^o 7). E, the stones cramped; F, the cramps; G, the middle part filled up.—N^o 8. represents another sort of compound masonry, the middle of which is stone, and the edges boards.

All the kinds of masonry now in use may be reduced to these five, viz. bound masonry; that of brick-work, where the bodies and projectures of the stones inclose square spaces or pannels, &c. set with bricks; that de moilon, or small work, where the courses are equal, well squared, and their edges or beds ruffled; that where the courses are unequal; and that filled up in the middle with little stones and mortar.

Free-Masonry, denotes the system of mysteries and secrets peculiar to the society of free and accepted masons.

The origin of this society is very ancient; but we have no authentic account of the time when it was first instituted, or even what was the reason of such an association of people under the title of *Masons*, more than of any other mechanical profession.—In Dr Henry's history we find the origin of the Free Mason Society in Britain attributed to the difficulty found in former times, of procuring a sufficient number of workmen to build the multitude of churches, monasteries, and other religious edifices which the superstitution of those ages prompted the people to raise. Hence the masons were greatly favoured by the popes, and many indulgences were granted in order to augment their numbers. In times like those we speak of, it may well be supposed that such encouragement from the supreme pastors of the church must have been productive of the most beneficial effects to the fraternity; and hence the increase of the society may naturally be deduced. The Doctor quotes, in confirmation of this, the words of an author who was well acquainted with their history and constitution. "The Italians (says he), with some Greek refugees, and with them French, Germans, and Flemings, joined

Masonry. ed into a fraternity of architects, procuring papal bulls for their encouragement and their particular privileges; they styled themselves *Free-masons*, and ranged from one nation to another, as they found churches to be built: their government was regular; and where they fixed near the building in hand, they made a camp of huts. A surveyor governed in chief; every tenth man was called a *warden*, and overlooked each nine. The gentlemen in the neighbourhood, either out of charity or commutation of penance, gave the materials and carriages. Those who have seen the accounts in records of the charge of the fabrics of some of our cathedrals near 400 years old, cannot but have a great esteem for their economy, and admire how soon they erected such lofty structures."

By other accounts, however, the antiquity of masonry is carried up much higher, even as early as the building of Solomon's temple. In Britain the introduction of masonry has been fixed at the year 674, when glass-making was first introduced; and it appears indeed, that from this time many buildings in the Gothic style were erected by men in companies, who are said to have called themselves *free*, because they were at liberty to work in any part of the kingdom. Others have derived the institution of free masons from a combination among the people of that profession not to work without an advance of wages, when they were summoned from several counties, by writs of Edward III. directed to the sheriffs, to assist in rebuilding and enlarging the castle, together with the church and chapel of St George at Windsor. At this time, it is said, the masons agreed on certain tokens by which they might know and assist each other against being imposed, and not to work unless free and on their own terms.

In a treatise on Masonry published in 1792 by William Preston, master of the Lodge of Antiquity, the origin of masonry is traced from the creation. "Ever since symmetry began, and harmony displayed her charms (says he), our order has had a being." Its introduction into England he likewise supposes to have been prior to the Roman invasion. There are, according to him, the remains yet existing, of some stupendous works executed by the Britons much earlier than the time of the Romans; and even these display no small share of ingenuity of invention: so that we can have no doubt of the existence of masonry in Britain even during these early periods. The Druids are likewise said to have had among them many customs similar to those of the masons, and to have derived their government from Pythagoras; but the resemblance betwixt their usages and those of the free-mason societies now existing cannot be accurately traced even by the masons themselves.

Masonry is said to have been encouraged by Cæsar, and many of the Roman generals who were appointed governors of Britain: but though we know, that at this period the fraternity were employed in erecting many magnificent fabrics, nothing is recorded concerning their lodges and conventions; and we have but a very imperfect account of the customs which prevailed in their assemblies.

For a long time the progress of masonry in Britain was obstructed by the frequent wars which took place; and it did not revive till the time of Carausius,

by whom it was patronised. This general, who hoped to be the founder of a British empire, encouraged learning and learned men; collecting also the best artificers from many different countries, particularly masons, whom he held in great veneration, and appointing Albanus his steward the principal superintendent of their assemblies. Lodges, or conventions of the fraternity, began now to be introduced, and the business of masonry to be regularly carried on. The masons, through the influence of Albanus, obtained a charter from Carausius to hold a general council, at which Albanus himself sat president, and assisted at the reception of many new members. This Albanus was the celebrated St Alban, the first who suffered martyrdom in Britain for the Christian faith. Mr Preston quotes an old MS. destroyed with many others, said to have been in the possession of Nicholas Stone, a curious sculptor under Inigo Jones; from which we learn that St Alban was a great friend to masons, and gave them two shillings per week besides threepence for their cheer; while, before that time, they had no more than one penny per day and their meat. He likewise obtained "a charter from the king and his council for them to hold a general council, which was named an *assembly*." The same circumstances are mentioned in a MS. written in the time of James II. only this increases the weekly salary of the masons to 3s. 6d. and 3d. per day for the bearers of burthens.

The progress of masonry was greatly obstructed by the departure of the Romans from Britain; and in a short time fell into absolute neglect. This was occasioned first by the furious irruptions of the Scots and Picts, which left no time for the cultivation of the arts; and afterwards by the ignorance of the Saxons, whom the ill-advised Britons called in as allies, but who soon became their masters. After the introduction of Christianity, however, the barbarity of these conquerors began to wear off, the arts received some encouragement, and masonry particularly began to flourish. Lodges were now formed; but these being under the direction of foreigners, were seldom convened, and never attained to any degree of consideration or importance. In this situation it continued till the year 557, when St Austlin, with 40 more monks, among whom the sciences had been preserved, came into England. By these the principles of Christianity were propagated with such zeal, that all the kings of the heptarchy were converted; after which masonry was taken under the patronage of St Austlin, and the Gothic style of building was introduced into England by the numerous foreigners who resorted at this time to the kingdom. Austlin himself appeared at the head of the fraternity in founding the old cathedral of Canterbury in 600; that of Rochester in 602; St Paul's in London in 604; St Peter's in Westminster in 605, as well as many others. The number of masons in England was thus greatly increased, as well as by his other buildings of castles, &c. throughout the kingdom.

In 640 a few expert brethren arrived from France, and formed themselves into a lodge under the direction of Bennet abbot of Wirral; whom Kenred king of Mercia soon after appointed inspector of the lodges, and general superintendent of the masons. During

Masonry

the whole time of the heptarchy, however, masonry was in a low state, but began to revive in 856 under the patronage of St Swithin, whom Ethelwolf employed to repair some religious houses; and from that time the art gradually improved till the year 872, when it found a zealous protector in Alfred the Great. This prince was a most eminent patron of all kinds of arts and manufactures; and, with regard to masonry in particular, he appropriated a seventh part of his revenue for maintaining a number of workmen, whom he constantly employed in rebuilding the cities, castles, &c. ruined by the Danes. During the reign of his successor Edward, the masons continued to hold their lodges under the sanction of Ethred, husband to the king's sister, and Ethelward his brother, to whom the care of the fraternity was intrusted. The latter was a great architect, and founded the university of Cambridge.

The true re-establishment of masonry in England, however, is dated from the reign of King Athelstane; and there is still extant a grand lodge of masons at York, who trace their existence from this period. This lodge, the most ancient in England, was founded in 926, under the patronage of Edwin the king's brother, who obtained for them a charter from Athelstane, and became grand master himself. By virtue of this charter it is said, that all the masons in the kingdom were convened at a general assembly in that city, where they established a general or grand lodge for their future government. Under the patronage and jurisdiction of this lodge it is also alleged that the fraternity increased very considerably, and that kings, princes, and other eminent persons who had been initiated into the mysteries, paid due allegiance to the assembly. But as the times were yet turbulent and barbarous, the art of masonry was sometimes more sometimes less patronised; and of course the assembly more or less respected according to the respect which the art itself met with. The appellation of *ancient York masons* is well known both in Ireland and Scotland; and the general tradition is, that they originated at Auldby near York; and as Auldby was a seat of Edwin, this tradition gives considerable confirmation to the above account. There is indeed great reason to believe that York was the original seat of masonic government, no other place having claimed it, and the whole fraternity having at various times owned allegiance to the authority there established; though we know not whether that allegiance be now given or not. Certain it is, that if such a lodge was once established there, of which there is no reason to doubt, we have no account of its being regularly moved from that place to any other part of the kingdom with consent of its members. Many respectable meetings have indeed been held at different times in other parts of the kingdom, but there is no account of any other general meeting being held in another place than York till very lately.

While prince Edwin lived, the masons were employed as formerly in building churches, monasteries, &c. and repairing those which had suffered by the ravages of the Danes; and after his death the order was patronised by king Athelstane himself; but on his decease the masons were dispersed, and remained in an unsettled state till the reign of Edgar in 960. They

Masonry

were now collected by St Dunstan, who employed them in works of the same kind; but as no permanent encouragement was given them, their lodges soon declined, and masonry remained in a low state for upwards of 50 years. It revived, however, in 1041, under Edward the Confessor, who superintended the execution of several great works. By the assistance of Leofrick earl of Coventry, he rebuilt Westminster Abbey, the earl being appointed superintendent of the masons; and by this architect many other magnificent structures were likewise erected. After the Conquest, in 1066, Gundulph bishop of Rochester and Roger de Montgomery earl of Shrewsbury, both of them excellent architects, became joint patrons of the masons; and under their auspices the Tower of London was begun, though finished only in the reign of William Rufus, who likewise rebuilt London Bridge with wood, and in 1087 first constructed the palace and hall of Westminster.

The masons now continued to be patronised by the sovereigns of England in succession. The lodges assembled during the reign of Henry I. and during that of Stephen, the society were employed in building a chapel at Westminster, now the House of Commons, and several other works; the president of the lodges being now Gilbert de Clare, the marquis of Pembroke. During the reign of Henry II. the lodges were superintended by the grand-master of the Knights Templars, who employed them in building their temple in Fleet-Street in the year 1155. Masonry continued under the patronage of this order till the year 1199, when John succeeded Richard I. in the throne of England, and Peter de Colechurch was then appointed grand-master. He began to rebuild London bridge with stone, which was afterwards finished by William Alemain in 1209. Peter de Rupibus succeeded Peter de Colechurch in the office of grand-master, and Geoffrey Fitz-Peter, chief surveyor of the king's works, acted as deputy under him; masonry continued also to flourish under the auspices of these two artists during this and the following reign. On the accession of Edward I. in 1272, the superintendence of the masons was entrusted to Walter Giffard archbishop of York, Gilbert de Clare earl of Gloucester, and Ralph lord of Mount Hermer, the progenitor of the family of the Montagues; and by these architects the abbey of Westminster was finished, after having been begun in 1220, during the minority of Henry II. During the reign of Edward II. the fraternity were employed in building Exeter and Oriol Colleges in Oxford, Clare-hall in Cambridge, &c. under the auspices of Walter Stapleton bishop of Exeter, who had been appointed grand-master of the masons in 1307.

Edward III. was a great encourager of learning in general, and not only patronised the masons, but applied very assiduously to the constitutions of the order, revised and meliorated the ancient charges, and added several useful regulations to the original code by which the fraternity had been governed. He patronised the lodges, and appointed five deputies under him to inspect their proceedings; and at this period it appears from some old records, that the lodges were numerous, and that the fraternity held communications under the protection of the civil magistrates. William a Wykeham was continued grand-master on the accession of Richard

Masonry. Richard II. and by him both the New College in Oxford and Winchester College were founded at his own expense. After the accession of Henry IV. Thomas Fitz-Allan earl of Surrey was appointed grand-maſter, who, after the engagement at Shrewsbury, founded Battle-abbey and Fotheringay; the Guildhall at London being alſo built in this reign. On the acceſſion of Henry V. the fraternity were directed by Henry Chicheley archbiſhop of Canterbury, under whom the lodges and communications of the fraternity were frequent. In 1425, however, during the reign of Henry VI. an act was made againſt the meetings of the chapters and congregations of maſons, becauſe it was ſaid, that by ſuch meetings “the good courſe and effect of the ſtatutes of labourers were openly violated and broken, in ſubverſion of the law, and to the great damage of all the commons.” But this act was not put in force, nor did the fraternity ceaſe to meet as uſual under the protection of archbiſhop Chicheley, who ſtill continued to preſide over them. The reaſon of this extraordinary edict is ſaid to have been as follows. The duke of Bedford, at that time regent of the kingdom, being in France, the regal power was veſted in his brother Humphrey duke of Glouceſter, who was ſtyled protector and guardian of the kingdom. The care of the young king’s perſon and education was entrusted to Henry Beaufort biſhop of Wincheſter, the duke’s uncle. This prelate being of an ambitious diſpoſition, and aſpiring at the ſole government, had continual diſputes with his nephew the protector; and by reaſon of the violent temper of that prince, gained frequent advantages over him. This animosity increaſed to ſuch a degree, that the parliament was at length obliged to interpoſe. On the meeting of that aſſembly in the month of April 1425, however, the ſervants and followers of the peers came thither, armed with clubs and ſtaves; on which account it received the name of the *Bat Parliament*, and at this time the act againſt maſons was made. This was owing to the influence of the biſhop, who wiſhed to deſtroy the meetings of the fraternity on account of the ſecrecy obſerved in them. Dr Anderſon, in the firſt edition of the Book of Conſtitutions, makes the following obſervation upon this act: “It was made in ignorant times, when true learning was a crime, and geometry condemned for conjuration; but it cannot derogate from the honour of the ancient fraternity, who, to be ſure, would never encourage any ſuch confederacy of their working brethren. By tradition, it is believed that the parliament were then too much influenced by the illiterate clergy, who were not accepted of maſons, nor underſtood architecture (as the clergy of ſome former ages), and were generally thought unworthy of this brotherhood. Thinking they had an inalienable right to know all ſecrets by virtue of auricular confeſſion, and the maſons never confeſſing any thing thereof, the ſaid clergy were highly offended; and at firſt, ſuſpecting them of wickedneſs, repreſented them as dangerous to the ſtate during that minority; and ſoon influenced the parliament to lay hold of ſuch ſuppoſed arguments of the working maſons for making an act that might ſeem to reflect diſhonour upon even the whole fraternity, in whole favour ſeveral acts had been made before that period, and were made after it.”

The biſhop was ſoon after this diverted from his perſecution of the maſons by an affair of a more important kind. He had formed a deſign of ſurpriſing the city of London on the evening of St Simon and St Jude’s day, that on which the Lord Mayor was inveſted with his office. But the plot having been diſcovered by the duke of Glouceſter, the Mayor was ſent for while at dinner, and ordered to keep a ſtrict watch for that night. The biſhop’s party accordingly made an attempt to enter by the bridge about nine the next morning, but were repulſed by the vigilance of the citizens. At this the prelate was ſo much enraged, that he collected a numerous body of archers and men at arms, commanding them to aſſault the gate with ſhot. By the prudence of the magiſtrates, however, all violent meaſures were ſtopped; but no reconciliation could be procured betwixt the two parties, though it was attempted by the archbiſhop of Canterbury, and Peter duke of Coimbra, eldeſt ſon to the king of Portugal, with ſeveral other perſons of diſtinction. At laſt the biſhop wrote a letter to the duke of Bedford, urging his return to England, and informing him of the danger there was of a civil war, and reflecting upon the duke of Glouceſter. This letter had the deſired effect. The regent returned, and held a great council at St Albans on the 21ſt of February, but adjourned it to the 15th of March at Northampton, and to the 25th of June at Leiſceſter. Bats and ſtaves were now prohibited at theſe meetings; but the parties aſſembled with weapons no leſs formidable, viz. with ſlings, ſtones, and leaden plummetts. The duke of Bedford employed all his authority to reconcile the differences; and at laſt obliged the two rivals to promiſe before the aſſembly that they would bury all animosities in oblivion. During the diſcuſſion of this matter five charges were exhibited by the duke of Glouceſter againſt the biſhop; one of which was, that “he had, in his letter to the duke of Bedford, at France, plainly declared his malicious purpoſe of aſſembly the people, and ſtirring up a rebellion in the nation, contrary to the king’s peace.” To this the biſhop answered, “That he never had any intention to diſturb the peace of the nation or raiſe a rebellion; but that he ſent to the duke of Bedford to ſolicit his return to England, to ſettle all thoſe differences which were ſo prejudicial to the peace of the kingdom: That though he had indeed written in the letter, ‘That if he tarried, we ſhould put the land in adventure by a field, ſuch a brother you have here,’ he did not mean it of any deſign of his own, but concerning the ſeditious aſſemblies of maſons, carpenters, tylers, and plaiſterers; who being diſtreſſed by the late act of parliament againſt the exceſſive wages of theſe trades, had given out many ſeditious ſpeeches and menaces againſt certain great men, which tended much to rebellion.” &c.

Notwithstanding this heavy charge, the duke of Glouceſter, who knew the innocence of the parties accuſed, took the maſons under his protection, and transferred the charge of ſedition and rebellion from them to the biſhop and his followers. By the intereſt of the latter, however, the king granted him a pardon for all offences; and though the duke drew up freſh articles of impeachment againſt him in 1442, and preſented them in perſon to the king, the council, being

compoſed

Masonry. composed mostly of ecclesiastics, proceeded so slowly in the business, that the duke, wearied out with the tediousness of the matter, dropped the prosecution entirely.

This contest terminated in the impeachment, imprisonment, and murder of the duke of Gloucester himself. This event might have been attended with bad consequence, had not their inveterate enemy, the prelate himself, been taken off by death in about two months after the duke. The masons then continued not only to meet in safety, but were joined by the king himself. He was, that very year (1442) initiated into masonry, and from that time spared no pains to become completely master of the art. He perused the ancient charges, revised the constitutions, and, with the consent of his council, honoured them with his sanction. The example of the sovereign was followed by many of the nobility, who assiduously studied the art. The king presided over the lodges in person, nominating William Wanefleet bishop of Winchester grand-master. This bishop at his own expence built Magdalene college, Oxford, and several religious houses. Eton-college near Windsor, and King's-college at Cambridge, were also founded during this reign. Henry himself founded Christ's-college, Cambridge, as his queen Margaret of Anjou did Queen's-college in the same university.

About this time also, the masons were protected and encouraged by James I. of Scotland, who, after his return from captivity, became a zealous patron of arts and learning of all kinds. He honoured the lodges with his royal presence, and settled an annual revenue of four pounds Scots (an English noble) to be paid by every master-mason in Scotland, to a grand-master chosen by the grand-lodge, and approved by the crown, one nobly born, or an eminent clergyman who had his deputies in cities and counties: something was likewise paid him by every new brother at his entry. His office intitled him to regulate every thing in the fraternity which could not come under the jurisdiction of law-courts; and, to prevent law-suits, both mason and lord, or builder and founder, appealed to him. In his absence, they appealed to his deputy or grand-warden, who resided next the premises.

The flourishing state of masonry was interrupted by the civil wars between the houses of York and Lancaster, which brought it almost totally into neglect. About 1471, however, it revived under the auspices of Robert Beauchamp bishop of Sarum, who had been appointed grand-master by Edward IV. and honoured with the title of *Chancellor of the Garter*, for repairing the castle and chapel of Windsor. It again declined during the reigns of Edward V. and Richard III.; but came once more into repute on the accession of Henry VII. in 1485. It was now patronised by the master and fellows of the order of St John at Rhodes (now Malta); who assembled their grand-lodge in 1500, and chose Henry for their protector. On the 24th of June 1502, a lodge of masters was formed in the palace, at which the king presided as grand-master; and having appointed John Islip abbot of Westminster, and Sir Reginald Bray knight of the garter, his wardens for the occasion, proceeded in great state to the east end of Westminster abbey,

where he laid the first stone of that excellent piece of Gothic architecture called *Henry the Seventh's Chapel*. The cape-stone of this building was celebrated in 1507. The palace of Richmond, as well as many other noble structures, were raised under the direction of Sir Reginald Bray; and the colleges of Brazen-Nose in Oxford, and Jesus and St John's in Cambridge, were all finished in this reign.

On the accession of Henry VIII. Cardinal Wolsey was appointed grand-master; who built Hampton-court, Whitehall, Christ-church college, Oxford, with several other noble edifices; all of which, upon the disgrace of that prelate, were forfeited to the crown in 1530: Wolsey was succeeded as grand-master in 1534 by Thomas Cromwell earl of Essex; who employed the fraternity in building St James's palace, Christ's hospital, and Greenwich castle. Cromwell being beheaded in 1540, John Touchet lord Audley succeeded to the office of grand-master, and built Magdalen college in Cambridge, and many other structures. In 1547, the duke of Somerset, guardian to the king, and regent of the kingdom, became superintendant of the masons, and built Somerset-house in the Strand; which, on his being beheaded, was forfeited to the crown in 1552.

After the death of the duke of Somerset, John Poynter bishop of Winchester presided over the lodges till the death of the king in 1553. From this time they continued without any patron till the reign of Elizabeth, when Sir Thomas Sackville accepted of the office of grand-master. Lodges, however, had been held during this period in different parts of England; but the general or grand lodge assembled in the city of York, where it is said the fraternity were numerous and respectable.—Of the queen we have the following curious anecdote with regard to the masons: Hearing that they were in possession of many secrets which they refused to disclose, and being naturally jealous of all secret assemblies, she sent an armed force to York to break up their annual grand-lodge. The design was prevented by the interposition of Sir Thomas Sackville, who took care to initiate some of the chief officers whom she had sent on this duty in the secrets of masonry. These joined in communication with their new brethren, and made so favourable a report to the queen on their return, that she countermanded her orders, and never afterwards attempted to disturb the meeting of the fraternity. In 1567, Sir Thomas Sackville resigned the office of grand-master in favour of Francis Russel earl of Bedford, and Sir Thomas Gresham an eminent merchant. The former had the care of the brethren in the northern part of the kingdom assigned to him, while the latter was appointed to superintend the meetings in the south, where the society had considerably increased, in consequence of the honourable report which had been made to the queen. The general assembly, however, continued to meet at York as formerly; and here all records were kept, and appeals made on every important occasion to the assembly.

Sir Thomas Gresham abovementioned proposed to erect a building in the city of London for the benefit of commerce, provided the citizens would purchase a spot proper for the purpose. Accordingly some

houses

Masonry.

Masonry houses between Cornhill and Threadneedle-street being pulled down, the foundation-stone of the building was laid on the 7th of June 1566, and with such expedition was the work carried on, that the whole was finished in November 1567. This building, which was constructed on the plan of the exchange of Antwerp, was called at first simply *the Bourfe*, but in January 1570, the queen having dined with Sir Thomas, returned through Cornhill, entered the Bourfe on the south side, and having viewed every part of the building, particularly the gallery which extended round the whole structure, and which was furnished with shops filled with all sorts of the finest merchandize in the city, she caused the edifice to be proclaimed, in her presence, by herald and trumpet, the *Royal Exchange*; and on this occasion, it is said Sir Thomas appeared publicly in the character of grand-master.

The queen being now thoroughly convinced that the fraternity of masons did not interfere in state affairs, became quite reconciled to their assemblies, and from this time masonry made a considerable progress; lodges were held in different parts of the kingdom, particularly in London and its neighbourhood, where the number of the brethren increased considerably. Several great works were carried on there under the auspices of Sir Thomas Gresham, from whom the fraternity received every encouragement.

Sir Thomas was succeeded in the office of grand-master by Charles Howard earl of Effingham, who continued to preside over the lodges in the fourth till the year 1588, when George Hastings earl of Huntingdon was chosen grand-master, and remained in the office till the decease of the queen in 1603.

On the accession of James I. to the crown of England, masonry flourished in both kingdoms, and lodges were held in both kingdoms. A number of gentlemen returned from their travels, with curious drawings of the old Greek and Roman architecture, as well as strong inclination to revive a knowledge of it. Among these was the celebrated Inigo Jones, who was appointed general surveyor to the king. He was named grand-master of England, and was deputed by the king to preside over the lodges (A). Several learned men were now initiated into the mysteries of masonry, and the society increased considerably in reputation and consequence. Ingenious artists resorted to England in great numbers; lodges were constituted as seminaries of instruction in the sciences and polite arts after the model of the Italian schools; the communications of the fraternity were established, and the annual festivals regularly observed. Under the direction of this accomplished architect, many magnificent structures were raised; and among the rest he was employed, by command of the sovereign, to plan a new palace at Whitehall, worthy of the residence of the kings of England. This was executed; but for want of a parliamentary fund, no more of the plan was ever finished than the banqueting-house. Inigo Jones continued in the office of grand-master till the year 1618, when he was succeeded by the earl of Pembroke; under whose auspices many eminent and weal-

thy men were initiated, and the mysteries of the order held in high estimation.

After Charles I. ascended the throne, Earl Pembroke was continued in his office till the year 1630, when he resigned in favour of Henry Danvers earl of Danby. This nobleman was succeeded in 1633 by Thomas Howard earl of Arundel, the ancestor of the Norfolk family. In 1633, Francis Russell earl of Bedford accepted the government of the society; but Inigo Jones having continued to patronize the lodges during his lordship's administration, he was re-elected the following year, and continued in office till the year of his death, 1646. The progress of masonry, however, was for some time obstructed by the breaking out of the civil wars; but it began to revive under the patronage of Charles II. who had been received into the order during his exile. Some lodges during this reign were constituted by leave of the several noble grand-masters, and many gentlemen and famous scholars requested at that time to be admitted into the fraternity. On the 27th of December 1603, a general assembly was held, where Henry Jennyn earl of St Alban's was elected grand-master; who appointed Sir John Denham his deputy, and Mr Christopher Wren, afterwards the celebrated Sir Christopher Wren, and John Webb, his wardens. At this assembly several useful regulations were made, for the better government of the lodges; and the greatest harmony prevailed among the whole fraternity. The earl of St Alban's was succeeded in his office of grand-master by earl Rivers in the year 1666, when Sir Christopher Wren was appointed deputy, and distinguished himself beyond any of his predecessors in promoting the prosperity of the lodges which remained at that time, particularly that of St Paul's, now the lodge of Antiquity, which he patronized upwards of 18 years. At this time he attended the meetings regularly; and during his presidency made a present to the lodge of three mahogany candlesticks, which at that time were very valuable. They are still preserved, and highly valued as a testimony of the esteem of the donor.

The fire which in 1666 destroyed such a great part of London, afforded ample opportunity for the masons to exert their abilities. After a calamity so sudden and extensive, however, it became necessary to adopt some regulations to prevent such a catastrophe in time to come. It was now determined, that in all the new buildings to be erected, stone should be used instead of timber. Wren was ordered by the king and grand-master to draw up the plan of a city with broad and regular streets. Dr Christopher Wren was appointed surveyor-general and principal architect for rebuilding the city, the cathedral of St Paul, and all the parochial churches enacted by parliament, in lieu of those that were destroyed, with other public structures. This gentleman, however, conceiving the charge to be too important for a single person, selected for his assistant Mr Robert Hook professor of geometry in Gresham college. The latter was immediately employed in measuring, adjusting, and setting out the ground.

(A) Mr Preston observes, that the grand-master of the north bears the title of *grand-master of all England*, which (says he) may probably have been occasioned by the title of *grand-master*.

Masonry.

ground of the private streets to the several proprietors. The model and plan were laid before the king and house of commons, and the practicability of the whole scheme, without any infringement of private property: but unfortunately it happened, that the greater part of the citizens were totally averse to leaving their old habitations, and building houses in other places; and so obdurate were they in their determinations, that they chose rather to have their old city again under all its disadvantages, than a new one upon the improved plan. Thus an opportunity was lost of making the new city the most magnificent as well as the most convenient for health and commerce of any in Europe. Hence the architect, being cramped in the execution of his plan, was obliged to alter and abridge it, and to model the city after the manner in which it has since appeared.—In 1673 the foundation-stone of the cathedral of St Paul's was laid with great solemnity by the king in person, and the mallet which he used on this occasion is still preserved in the lodge of Antiquity as a great curiosity.

During the time that the city was rebuilding, lodges were held by the fraternity in different places, and many new ones constituted, to which the best architects resorted. In 1674, earl Rivers resigned the office of grand-master in favour of George Villiers duke of Buckingham, who left the care of the fraternity to his wardens, and Sir Christopher Wren who still continued to act as deputy. In 1679, the duke resigned in favour of Henry Bennet earl of Arlington; but this nobleman was too deeply engaged in state affairs to attend to his duty as a mason, though the lodges continued to meet under his sanction, and many respectable gentlemen joined the fraternity. During the short reign of James II. the masons were much neglected. In 1685, Sir Christopher Wren was elected to the office of grand-master, who appointed Gabriel Cibber and Mr Edward Strong his wardens: yet notwithstanding the great reputation and abilities of this celebrated architect, masonry continued in a declining way for many years, and only a few lodges were held occasionally in different parts of the kingdom.

At the Revolution, the society was in such a low state in the south of England, that only seven regular lodges were held in London and its suburbs; and of these only two, viz. that of St Paul's and one at St Thomas's hospital, Southwark, were of any consequence. But in 1695 king William having been initiated into the mysteries, honoured the lodges with his presence, particularly one at Hampton-court, at which he is said to have frequently presided during the time that the new part of his palace was building. Many of the nobility also were present at a general assembly and feast held in 1697, particularly Charles duke of Richmond and Lenox, who was elected grand-master for that year; but in 1698 resigned his office to Sir Christopher Wren, who continued at the head of the fraternity till King William's death in 1702.

During the reign of Queen Anne, masonry made no considerable progress. Sir Christopher's age and infirmities drew off his attention from the duties of his office, the annual festivals were entirely neglected, and the number of masons considerably diminished. It was therefore determined that the privileges of ma-

sonry not be confined to operative masons, but that people of all professions should be admitted to participate in them, provided they were regularly approved and initiated into the order.

Masonry.

Thus the society once more rose into esteem; and on the accession of George I. the masons, now deprived of Sir Christopher Wren, resolved to unite again under a grand-master, and revive the annual festivals. With this view, the members of the only four lodges at that time existing in London, met at the Apple-tree tavern in Charles-street, Covent Garden; and having voted the oldest master-mason then present into the chair, constituted themselves a grand-lodge *pro tempore*. It was now resolved to renew the quarterly communications among the brethren; and at an annual meeting held on the 24th of June the same year, Mr Anthony Sayer was elected grand-master, invested by the oldest master-mason then present, installed by the master of the oldest lodge, and had due homage paid him by the fraternity. Before this time a sufficient number of masons, met together within a certain district, had ample power to make masons without a warrant of constitution; but it was now determined, that the privilege of assembling as masons should be vested in certain lodges or assemblies of masons convened in certain places, and that every lodge to be afterwards convened, excepting the four old lodges then existing, should be authorized to act by a warrant from the grand-master for the time, granted by petition from certain individuals, with the consent and approbation of the grand-lodge in communication; and that without such warrant, no lodge should hereafter be deemed regular or constitutional. The former privileges, however, were still allowed to remain to the four old lodges then extant. In consequence of this, the old masons in the metropolis vested all their inherent privileges as individuals in the four old lodges, in trust that they never would suffer the ancient charges and land-marks to be infringed. The four old lodges, on their part, agreed to extend their patronage to every new lodge which should hereafter be constituted according to the new regulations of the society; and while they acted in conformity to the ancient constitutions of the order, to admit their masters and wardens to share with them all the privileges of the grand-lodge, that of precedence only excepted.

Matters being thus settled, the brethren of the four old lodges considered their attendance on the future communications of the society as unnecessary; and therefore trusted implicitly to their masters and wardens, satisfied that no measure of importance would be adopted without their approbation. It was, however, soon discovered, that the new lodges being equally represented with the old ones at the communications, would at length so far outnumber them, that by a majority they might subvert the privileges of the original masons of England which had been centered in the four old lodges; on which account a code of laws was, with the consent of the brethren at large, drawn up for the future government of the society. To this the following was annexed, binding the grand-master for the time being, his successors, and the master of every lodge to be hereafter constituted, to preserve it inviolably; "Every annual grand-lodge has

Masonry.

an inherent power and authority to make new regulations, or to alter these for the real benefit of this ancient fraternity, provided always that the old landmarks be carefully preserved: and that such alterations and new regulations be proposed and agreed to at the third quarterly communication preceding the annual grand feast; and that they be offered also to the perusal of all the brethren before dinner, in writing, even of the youngest apprentice; the approbation and consent of the majority of all the brethren present being absolutely necessary to make the same binding and obligatory." To commemorate this circumstance, it has been customary, ever since that time, for the master of the oldest lodge to attend every grand installation; and, taking precedence of all present, the grand-master only excepted, to deliver the book of the original constitutions to the new installed grand-master, on his promising obedience to the ancient charges and general regulations.

By this precaution the original constitutions were established as the basis of all succeeding masonic jurisdiction in the south of England; and the ancient *landmarks*, as they are called, or the boundaries set up as checks against innovation, were carefully secured from the attacks of any future invaders. No great progress, however, was made during the administration of Mr Sayer, only two lodges being constituted, though several brethren joined the old ones. In 1718 Mr Sayer was succeeded by Mr George Payne, who collected many valuable manuscripts on the subject of masonry, and earnestly requested, that the fraternity would bring to the grand lodge any old writings or records concerning the fraternity, to show the usages of ancient times: and in consequence of this invitation, several old copies of the Gothic constitutions were produced, arranged, and digested. Another assembly and feast were held on the 24th of June 1719, when Dr Desaguliers, was unanimously elected grand-master. At this feast the old, regular, and peculiar toasts were introduced; and from this time we may date the rise of free-masonry on its present plan in the south of England. Many new lodges were established, the old ones visited by many masons who had long neglected the craft, and several noblemen initiated into the mysteries. In 1720, however, the fraternity sustained an irreparable loss by the burning of several valuable manuscripts, concerning the lodges, regulations, charges, secrets, &c. (particularly one written by Mr Nicholas Stone, the warden under Inigo Jones). This was done by some scrupulous brethren, who were alarmed at the publication of the masonic constitutions. At a quarterly communication it was this year agreed, that, for the future, the new grand-master shall be named and proposed to the grand lodge some time before the feast; and if approved and present, he shall be saluted as grand-master elect: and that every grand-master, when he is installed, shall have the sole power of appointing his deputy and wardens according to ancient custom.

In the mean time masonry continued to spread in the north as well as the south of England. The general assembly, or grand lodge at York, continued to meet as usual. Several lodges met in 1705, under the direction of Sir John Tempest baronet, then grand-master; and many persons of worth and character were

Masonry.

initiated into the mysteries of the fraternity. The greatest harmony subsisted between the two grand lodges, and private lodges were formed in both parts of the kingdom under their separate jurisdiction. The only distinction which the grand lodge in the north appears to have retained is in the title of the *Grand Lodge of all England*; while the other was only called the *Grand Lodge of England*. The latter, however, being encouraged by some of the principal nobility, soon acquired consequence and reputation, while the other seemed gradually to decline; but, till within these few years, the authority of the grand lodge at York was never challenged; on the other hand, every mason in the kingdom held that assembly in the highest veneration, and considered himself bound by the charges which originated from that assembly. It was the glory and boast of the brethren in almost every country where masonry was established to be accounted descendants of the original York masons; and from the universality of the idea that masonry was first established at York by charter, the masons of England have received tribute from the first states in Europe. At present, however, this social intercourse is abolished, and the lodges in the north and south are almost entirely unknown to one another; and neither the lodges of Scotland nor Ireland court the correspondence of the grand lodge at London. This is said to have been owing to the introduction of some innovations among the lodges in the south; but for the coolness which subsists between the two grand lodges another reason is assigned. A few brethren at York having, on some trivial occasion, seceded from their ancient lodge, they applied to London for a warrant of constitution. Their application was honoured without any inquiry into the merits of the case; and thus, instead of being recommended to the mother-lodge to be restored to favour, these brethren were encouraged to revolt, and permitted, under the sanction of the grand lodge in London, to open a new lodge in the city of York itself. This illegal extension of power justly offended the grand lodge at York, and occasioned a breach which has never yet been made up.

The duke of Buccleugh, who in 1723 succeeded the duke of Wharton as grand-master, first proposed the scheme of raising a general fund for distressed masons. The duke's motion was supported by Lord Paisley, Colonel Houghton, and a few other brethren; and the grand lodge appointed a committee to consider of the most effectual means of carrying the scheme into execution. The disposal of the charity was first vested in seven brethren; but this number being found too small, nine more were added. It was afterwards resolved that 12 masters of contributing lodges, in rotation with the grand officers, should form the committee; and by another regulation since made, it has been determined that all past and present grand officers, with the masters of all regular lodges which shall have contributed within 12 months to the charity, shall be members of the committee. This committee meets four times in the year by virtue of a summons from the grand master or his deputy. The petitions of the distressed brethren are considered at these meetings; and if the petitioner be considered as a deserving object, he is immediately relieved with five pounds. If the circumstances of the case are of

Masonry.

a peculiar nature, his petition is referred to the next communication, where he is relieved with any sum the committee may have specified, not exceeding 20 guineas at one time. Thus the distressed have always found ready relief from this general charity, which is supported by the voluntary contributions of different lodges out of their private funds, without being burdensome to any member in the society. Thus has the committee of charity for free masons been established; and so liberally have the contributions been, that though the sums annually expended for the relief of the distressed brethren have for several years past amounted to many thousand pounds, there still remains a considerable sum.

The most remarkable events which of late have taken place in the affairs of masonry, are the initiation of Omilul-Omrâh Bahauder, eldest son of the nabob of the Carnatic, who was received by the lodge of Trinchinopoly in the year 1779. The news being officially transmitted to England, the grand lodge determined to send a congratulatory letter to his highness on the occasion, accompanied with an apron elegantly decorated, and a copy of the book of Constitutions superbly bound. The execution of this commission was entrusted to Sir John Dwy, advocate-general of Bengal; and in the beginning of 1780, an answer was received from his highness, acknowledging the receipt of the present, and expressing the warmest attachment and benevolence to his brethren in England. The letter was written in the Persian language, and inclosed in an elegant cover of cloth of gold, and addressed to the grand-master and grand lodge of England. A proper reply was made; and a translation of his highness's letter was ordered to be copied on vellum; and, with the original, elegantly framed and glazed, and hung up in the hall at every public meeting of the society.

After such a long history of the rise and progress of masonry, it must be natural to inquire into the uses of the institution, and for what purpose it has been patronised by so many great and illustrious personages. The profound secrecy, however, in which every thing relating to masonry is involved, prevents us from being very particular on this head. The masons themselves say, in general, that it promotes philanthropy, friendship, and morality; that in proportion as masonry has been cultivated, the countries have been civilized, &c. How far this can be depended upon, the fraternity themselves best know. Another advantage, however, seems less equivocal, viz. that its signs serve as a kind of universal language, so that by means of them people of the most distant nations may become acquainted, and enter into friendship with one another. This certainly must be accounted a very important circumstance; and considering the great number which have been, and daily are, admitted to the society, and their inviolable attachment to the art, we must certainly conclude, that if it contains nothing of great importance to mankind at large, it must at least be extremely agreeable, and even fascinating to those who are once initiated.

Egyptian Masonry, a new system of masonry taught by the celebrated impostor the Count Cagliostro.—It is not known whether this system was an invention of his own, or whether any such thing really has an

existence among the superstitious Egyptians. The scheme was first put in execution in London; and by means of his pretended knowledge in the mysteries of this art, the Count procured great sums of money, and attached to himself a vast number of followers. The following particulars concerning it were confessed by him before the inquisition at Rome.

The Egyptian masons are divided into several sects, but there are two more esteemed than the rest. The first is that of the adepts, the members of which (say the inquisitors) profess the most irreligious sentiments, and employ magic in their operations; but their principal object is the destruction of the Catholic religion and of monarchy. The members of the other pretend to be occupied about the secrets of the hermetic art, and more especially the philosopher's stone. Cagliostro owned that he was associated in London with the second of these sects; that his wife was likewise a member, and received a diploma, which cost five guineas. The lady was presented with a ribbon, on which were embroidered the words *Union, Silence, and Virtue*; and she was desired to sleep the following night with the ribbon attached to her thigh. When a male candidate is to be admitted, his courage must be tried in a number of ways. Cagliostro himself submitted to these trials; among which the following are mentioned in the account of his life. He was first hoisted up to the cindling by means of a pulley, and, after suffering considerable pain, had his hand scorched by means of a candle. His eyes were then covered with a bandage, and he received an empty pistol, with orders to charge it. This being done, he was ordered to discharge it against his head; and upon his refusing to do so, the pistol was taken from him with contempt, but returned after a number of ceremonies. This had such an effect upon him, that without any regard to self-preservation, he drew the trigger, and got a smart stroke on the skull, which, however, produced no bad consequence. At the initiation of other candidates, he discovered that the pistol was changed, an unloaded one being put into the hands of the person when blind-folded, and that one of the assistants struck him a smart blow on the head, to make him think himself wounded. The ceremony was concluded with his taking an oath of secrecy and obedience to the grand-master.

MASORA, a term in the Jewish theology, signifying a work on the Bible, performed by several learned rabbins, to secure it from any alterations which might otherwise happen.

Their work regards merely the letter of the Hebrew text, in which they have, first, fixed the true reading by vowels and accents: they have, secondly, numbered not only the chapters and sections, but the verses, words, and letters of the text: and they find in the Pentateuch 5245 verses, and in the whole Bible 23206. The *mafora* is called, by the Jews, *the hedge or fence of the law*, because this enumeration of the verses, &c. is a means of preserving it from being corrupted and altered. They have, thirdly, marked whatever irregularities occur in any of the letters of the Hebrew text; such as the different size of the letters, their various positions and inversions, &c. and they have been fruitful in finding out reasons for these irregularities and mysteries in them. They are, fourthly, supposed to be

Masonry.
Mafora.

Masora.
Masque.

be the authors of the Keri and Chetibh, or the marginal corrections of the text in our Hebrew Bibles.

The text of the sacred books, it is to be observed, was originally written without any breaks or divisions into chapters or verses, or even into words; so that a whole book, in the ancient manner, was but one continued word; of this kind we have still several ancient manuscripts, both Greek and Latin. In regard, therefore, the sacred writings had undergone an infinite number of alterations, whence various readings had arisen, and the original was become much mangled and disguised, the Jews had recourse to a canon, which they judged infallible, to fix and ascertain the reading of the Hebrew text; and this rule they call *masora*, "tradition," from *tradidit*, as if this critique were nothing but a tradition which they had received from their forefathers. Accordingly they say, that when God gave the law to Moses at Mount Sinai, he taught him, first, the true reading of it; and, secondly, its true interpretation; and that both these were handed down by oral tradition, from generation to generation, till at length they were committed to writing. The former of these, viz. the true reading, is the subject of the *masora*; the latter, or true interpretation, that of the *mishtna* and *gemara*.

According to Elias Levita, they were the Jews of a famous school at Tiberias, about 500 years after Christ, who composed, or at least began, the *masora*; whence they are called *masorites*, and *masoretic doctors*. Aben Ezra makes them the authors of the points and accents in the Hebrew text, as we now find it; and which serve for vowels.

The age of the *masorites* has been much disputed. Archbishop Usher places them before Jerom; Capel, at the end of the fifth century; father Morin, in the tenth century. Bagnage says, that they were not a society, but a succession of men; and that the *masora* is the work of many grammarians, who, without associating and communicating their notions, composed this collection of criticisms on the Hebrew text. It is urged that there were *masorites* from the time of Ezra and the men of the great synagogue, to about the year of Christ 1030; and that Ben Asher and Ben Naphtali, who were the best of the profession, and who, according to Bagnage, were the inventors of the *masora*, flourished at this time. Each of these published a copy of the whole Hebrew text, as correct, says Dr Prideaux, as they could make it. The eastern Jews have followed that of Ben Naphtali, and the western that of Ben Asher; and all that has been done since is to copy after them, without making any more corrections, or *masoretic* criticisms.

The Arabs have done the same thing by their *Koran* that the *masorites* have done by the Bible; nor do the Jews deny their having borrowed this expedient from the Arabs, who first put it in practice in the seventh century.

There is a great and little *masora* printed at Venice and at Basil, with the Hebrew text in a different character. Buxtorf has written a *masoretic* commentary, which he calls *Tiberias*.

MASQUE, or MASK, a cover for the face, contrived with apertures for the eyes and mouth; originally worn chiefly by women of condition, either to preserve their complexion from the weather, or out of

Masque.

modesty to prevent their being known. Poppea, wife of Nero, is said to be the first inventor of the *masque*; which she did to guard her complexion from the sun and weather, as being the most delicate woman, with regard to her person, that has been known.

Theatrical *masques* were in common use both among the Greeks and Romans: Suidas and Athenæus ascribe the invention of them to the poet Choerilus, a contemporary of Thespis; Horace attributes them to Æschylus; but Aristotle informs us, that the real inventor, and consequently the time of their first introduction and use, were unknown. Brantome observes, that the common use of modern *masques* was not introduced till towards the end of the sixteenth century.

MASQUE is also used to signify any thing used to cover the face, and prevent a person's being known. The penitents of Lyons and Avignon hide their faces with large white veils, which serve them for *masques*.

The Iron *Masque* (*Masque de Fer*), or *Man with the iron masque*, a remarkable personage so denominated, who existed as a state prisoner in France during the latter part of the last century. As the circumstances of this person form a historical problem which has occasioned much inquiry, and given rise to many conjectures, as well as of late, in consequence of the destruction of the Bastille, excited in a particular manner the curiosity of the public, it shall be endeavoured to condense in this article the substance of every thing material that has been published on the subject. We shall first relate such particulars concerning this extraordinary prisoner as appear to be well authenticated; and shall afterwards mention the different opinions and conjectures that have been entertained with regard to his real quality, and the causes of his confinement.

I. The authenticated particulars concerning the *iron Masque* are as follows:—A few months after the death of Cardinal Mazarine, there arrived at the isle of Sainte Marguerite, in the sea of Provence, a young prisoner whose appearance was peculiarly attracting; his person was above the middle size, and elegantly formed; his mien and deportment were noble; and his manners graceful; and even the sound of his voice, it is said, had in it something uncommonly interesting. On the road he constantly wore a mask made with iron springs, to enable him to eat without taking it off. It was at first believed that this *masque* was made entirely of iron; whence he acquired the name of "the Man with the iron mask." His attendants had received orders to dispatch him if he attempted to take off his *masque* or discover himself.—He had been first confined at Pigneol, under the care of the governor M. de St Mars; and upon being sent from thence to Sainte Marguerite, he was accompanied thither by the same person, who continued to have the charge of him. He was always treated with the most marked respect: he was served constantly in plate; and the governor himself placed his dishes on the table, retiring immediately after and locking the door behind him. He *tu-to-yoit* (thee'd and thou'd) the governor; who, on the other hand, behaved to him in the most respectful manner, and never wore his hat before him, nor sat down in his presence unless he was desired. The Marquis de Louvois, who went to see him at St Marguerite, spoke to him standing, and with that kind of attention which denotes high respect.

During his residence here, he attempted twice, in an indirect manner, to make himself known. One day he wrote something with his knife on a plate, and threw it out of his window towards a boat that was drawn on shore near the foot of the tower. A fisherman picked it up and carried it to the governor. M. de St Mars was alarmed at the sight; and asked the man with great anxiety, whether he could read, and whether any one else had seen the plate? The man answered, that he could not read, that he had but just found the plate, and that no one else had seen it. He was, however, confined till the governor was well assured of the truth of his assertions.—Another attempt to discover himself proved equally unsuccessful. A young man who lived in the isle, one day perceived something floating under the prisoner's window; and on picking it up, he discovered it to be a very fine shirt written all over. He carried it immediately to the governor; who, having looked at some parts of the writing, asked the lad, with some appearance of anxiety, if he had not had the curiosity to read it? He protested repeatedly that he had not: but two days afterwards he was found dead in his bed.

The *Masque de Fer* remained in this life till the year 1698, when M. St Mars being promoted to the government of the Bastille, conducted his prisoner to that fortress. In his way thither, he stopt with him at his estate near Palteau. The Masque arrived there in a litter, surrounded by a numerous guard on horseback. M. de St Mars sat at the same table with him all the time they resided at Palteau; but the latter was always placed with his back towards the windows; and the peasants, who came to pay their compliments to their master, and whom curiosity kept constantly on the watch, observed that M. de St Mars always sat opposite to him with two pistols by the side of his plate. They were waited on by one servant only, who brought in and carried out the dishes, always carefully shutting the door both in going out and returning. The prisoner was always masked, even when he passed through the court; but the people saw his teeth and lips, and also observed that his hair was grey.—The governor slept in the same room with him, in a second bed that was placed in it on that occasion. In the course of their journey, the iron-mask was, one day, heard to ask his keeper whether the king had any design on his life? “No, Prince,” he replied; “provided that you quietly allow yourself to be conducted, your life is perfectly secure.”

The stranger was accommodated as well as it was possible to be in the Bastille. An apartment had been prepared for him by order of the governor before his arrival, fitted up in the most convenient style; and every thing he expressed a desire for was instantly procured him. His table was the best that could be provided; and he was ordered to be supplied with as rich clothes as he desired: but his chief taste in this last particular was for lace, and for linen remarkably fine. It appears that he was allowed the use of such books as he desired, and that he spent much of his time in reading. He also amused himself with playing upon the guitar. He had the liberty of going to mass; but was then strictly forbid to speak or uncover his face: orders were even given to the soldiers to fire upon

him if he attempted either; and their pieces were always pointed towards him as he passed through the court. When he had occasion to see a surgeon or a physician, he was obliged, under pain of death, constantly to wear his mask. An old physician of the Bastille, who had often attended him when he was indisposed, said, that he never saw his face, though he had frequently examined his tongue, and different parts of his body; that there was something uncommonly interesting in the sound of his voice; and that he never complained of his confinement, nor let fall from him any hint by which it might be guessed who he was. It is said that he often passed the night in walking up and down his room.

This unfortunate prince died on the 19th of November 1703, after a short illness; and was interred next day in the burying-place of the parish of St Paul. The expence of his funeral amounted only to forty livres. The name given him was *Marchiali*: and even his age, as well as his real name, it seemed of importance to conceal; for in the register made of his funeral, it was mentioned that he was about forty years old; though he had told his apothecary, some time before his death, that he thought he must be sixty.—It is a well known fact, that immediately after the prisoner's death, his apparel, linen, clothes, mattresses, and in short every thing that had been used by him, were burnt; that the walls of his room were scraped, the floor taken up, evidently from the apprehension that he might have found means of writing any thing that would have discovered who he was. Nay such was the fear of his having left a letter or any mark which might lead to a discovery, that his plate was melted down; the glass was taken out of the window of his room and pounded to dust; the window-frame and doors burnt; and the ceiling of the room, and the plaster of the inside of the chimney, taken down. Several persons have affirmed, that the body was buried without a head; and Monsieur de Saint Foix informs us, that “a gentleman having bribed the sexton, had the body taken up in the night, and found a stone instead of the head.”

The result of these extraordinary accounts is, that the iron masque was not only a person of high birth, but must have been of great consequence; and that his being concealed was of the utmost importance to the king and ministry. We come now, therefore, to notice,

II. The opinions and conjectures that have been formed concerning the real name and condition of this remarkable personage. Some have pretended that he was the duke of Beaufort; others, that he was the Count de Vermandois, natural son to Louis XIV. by the duchess de la Valliere. Some maintain him to have been the duke of Monmouth, natural son of Charles II. of England by Lucy Walters; and others say, that he was Gerolami Magni, minister to the duke of Modena.

Besides these conjectures, none of which possess sufficient probability to entitle them to consideration, a fifth has been advanced; namely, That the Iron Masque was a son of Anne of Austria, queen to Louis XIII. and consequently that he was a brother of Louis XIV.; but whether a bastard brother, a bro-

† In his *Essai sur l'Histoire*.

Masque.

ther-german, or a half brother, is a question that has given rise to three several opinions; which we shall state in the order of time in which the respective transactions to which they allude happened.

1. The first opinion is, that the queen proved with child at a time when it was evident it could not have been by her husband, who, for some months before, had never been with her in private. The supposed father of this child is said by some to have been the duke of Buckingham, who came to France in May 1625, to conduct the princess Henrietta, wife of Charles I. to England. The private letters and memoirs of those times speak very suspiciously of the queen and Buckingham: his behaviour at Amiens, whither the queen and queen-mother accompanied the princess in her way to Boulogne, occasioned much whispering; notwithstanding the pains that have been taken by La Porte in his *Mémoires* to excuse his mistress, it appears that the king, on this occasion, was extremely offended at her, and that it required all the influence and address of the queen-mother to effect a reconciliation. It is said, that this child was privately brought up in the country; that when Mazarin became a favourite, he was entrusted with the care of him; and that Louis XIV. having discovered the secret on the death of the cardinal, thought it necessary to confine him in the manner that has been related.

Hist. of the
Bastille, n° 6.
P. 343.

But it may be observed, that this secret could scarcely have escaped the vigilance of the cardinal de Richlieu; and it is not improbable, that a minister so little scrupulous, if inclined to save the honour of a queen, would have removed a child, who, if he lived, might have been made use of to disturb the tranquillity of the kingdom. After this supposed birth, the queen had frequent quarrels with the king, and, what was more dangerous, with the cardinal; who even used every means in his power to enquire into her most private transactions. It was on a memorable occasion of this kind, that her servant La Porte was thrown into the Bastille; and it can scarcely be imagined the would have had the firmness she then displayed, while conscious of so much guilt, and under the risk of having it discovered. The prisoner with the masque appears, by several accounts, to have been a youth of a handsome figure in the year 1661; and in 1703, when he died, to have been above sixty; but had he been a son of Buckingham, he would have been about thirty-six in 1661, when he could not be said to have been a youth; and in November 1703, above seventy-eight.

2. The second opinion is, that he was the twin-brother of Louis XIV. born some hours after him. This first appeared in a short anonymous work published without date, and without the name of place or printer. It is therein said, "Louis XIV. was born at St Germain en Laye, on the 5th of September 1638, about noon; and the illustrious prisoner, known by the appellation of the *Iron masque*, was born the same day, while Louis XIII. was at supper. The king and the cardinal, fearing that the pretensions of a

twin brother might one day be employed to renew those civil wars with which France had been so often afflicted, cautiously concealed his birth, and sent him away to be brought up privately. Having but an imperfect knowledge of the circumstances that followed, I shall say nothing more, for fear of committing errors; but I firmly believe the fact I have mentioned; and time will probably prove to my reader, that I have ground for what I have advanced."

Masque.

This opinion has been more noticed since the publication of a work called *Mémoires du Marechal Duc de Richlieu*, written by the Abbé Soulavie; concerning which it may be proper to premise, that the present duke of Richlieu, son of the marechal, disavows this work; while the Abbé Soulavie, who had been employed by the marechal, insists on the authenticity of his papers (A). He informs us, that the duke of Richlieu was the lover of Mademoiselle de Valois, daughter of the regent duke of Orleans, and afterwards duchess of Modena, who in return was passionately fond of him: that the regent had something more than a paternal affection for his daughter; and that, though he held his sentiments in abhorrence, the duke of Richlieu made use of her influence with her father to discover the secret of the prisoner with the masque: that the regent, who had always observed the most profound silence on this subject, was at last persuaded to entrust her with a manuscript, which she immediately sent to her lover, who took a copy of it. This manuscript is supposed to have been written by a gentleman on his death-bed, who had been the governor of the prisoner. The following is an extract of it, from what the Abbé Soulavie has told us.

"The birth of the prisoner happened in the evening of the 5th of September 1638, in presence of the chancellor, the bishop of Meaux, the author of the manuscript, a midwife named Peronette, and a few Honorat. This circumstance greatly disturbed the king's mind; he observed, that the Salique law had made no provision for such a case; and that it was even the opinion of some, that the last born was the first conceived, and therefore had a prior right to the other. By the advice of cardinal de Richlieu, it was therefore resolved to conceal his birth, but to preserve his life, in case by the death of his brother it should be necessary to avow him. A declaration was drawn up, and signed and sworn to by all present, in which every circumstance was mentioned, and several marks on his body described. This document being sealed by the chancellor with the royal seal, was delivered to the king; and all were commanded and took an oath never to speak on the subject, not even in private and among themselves. The child was delivered to the care of Madame Peronette the midwife, to be under the direction of cardinal de Richlieu, at whose death the charge devolved to cardinal de Mazarin. Mazarin appointed the author of the manuscript his governor, and entrusted to him the care of his education. But as the prisoner was extremely attached to Madame Peronette, and she equally so to him, she remained with him till her death. His governor carried him to his house in Burgundy,

(A) A letter from the duke of Richlieu, and an answer from the Abbé Soulavie, appeared in the Journal de Paris.

Masque.

gundy, where he paid the greatest attention to his education.

"As the prisoner grew up, he became impatient to discover his birth, and often importuned his governor on that subject. His curiosity had been roused, by observing that messengers from the court frequently arrived at the house; and a box, containing letters from the queen and the cardinal, having one day been inadvertently left out, he opened it, and saw enough to guess at the secret. From that time he became thoughtful and melancholy, 'which (says the author) I could not then account for. He shortly after asked me to get him a portrait of the late and present king, but I put him off by saying that I could not procure any that were good.' He then desired me to let him go to Dijon; which I have known since was with an intention of seeing a portrait of the king there, and of going secretly to St John de Lus, where the court then was on occasion of the marriage with the infant. He was beautiful; and love helped him to accomplish his wishes. He had captivated the affections of a young housekeeper, who procured him a portrait of the king. It might have served for either of the brothers; and the discovery put him into so violent a passion, that he immediately came to me with the portrait in his hand, saying, *Voilà mon frere, et voilà qui je suis*, showing me at the same time a letter of the cardinal de Mazarin that he had taken out of the box.' Upon this discovery his governor immediately sent an express to court to communicate what had happened, and to desire new instructions; the consequence of which was, that the governor and the young prince under his care were arrested and confined."

This memoir, real or fictitious, concludes with saying, "I have suffered with him in our common prison; I am now summoned to appear before my Judge on high; and for the peace of my soul I cannot but make this declaration, which may point out to him the means of freeing himself from his present ignominious situation, in case the king his brother should die without children. Can an extorted oath compel me to observe secrecy on a thing so incredible, but which ought to be left on record to posterity."

3. The third opinion is, that he was a son of the queen by the cardinal de Mazarin, born about a year after the death of her husband Louis XIII.; that he was brought up secretly; and that soon after the death of the cardinal, which happened on the 9th of March 1661, he was sent to Pignerol. To this account Father Griffet* objects, "that it was needless to masque a face that was unknown; and therefore that this opinion does not merit discussion." But in answer it has been observed, That the prisoner might strongly resemble Louis XIV. which would be a sufficient reason to have him masked. This opinion is supposed to have been that entertained by Voltaire, who asserts his thorough knowledge of the secret, though he declined being altogether explicit. The Abbé Soulavie, author of *Memoirs of the Marechal de Richlieu*, speaking on this subject, says, "That he once observed to the Marechal, that he certainly had the means of being informed who the prisoner was; that it even seemed that he had told Voltaire, who durst not venture to publish the secret; and that he at last asked him, whether he was not the elder brother of Louis XIV. born without

the knowledge of Louis the XIII.? That the marechal seemed embarrassed, but afterwards said, that he was neither the ballard brother of Louis the XIV. nor the duke of Monmouth, nor the count of Vermandois, nor the duke of Beaufort, as different authors had advanced; that their conjectures were nothing but reveries; but added, that they however had related many circumstances that were true; that in fact the order was given to put the prisoner to death if he discovered himself; and that he finished the conversation by saying, All I can tell you on the subject is, that the prisoner was not of such consequence when he died at the beginning of the present century as he had been at the beginning of the reign of Louis the XIV. and that he was shut up for important reasons of state." The Abbé Soulavie tells us, that he wrote down what had been said, and gave it to the Marechal to read, who corrected some expressions. The Abbé having proposed some further questions, he answered, "Read what Voltaire published last on the subject of the prisoner with the masque, especially at the end, and reflect on it."—The passage of Voltaire alluded to is as follows.

"The man with the masque (says he) is an enigma of which every one would guess the meaning. Some have said that it was the duke of Beaufort; but the duke of Beaufort was killed by the Turks in the defence of Candy in 1669, and the prisoner with the masque was at Pignerol in 1661. Besides, how could the duke of Beaufort have been arrested in the midst of his army, and brought to France, without any one knowing it? and why confine him? and why that mask?—Others have dreamed that he was the count de Vermandois, natural son of Louis XIV. who died publicly at the army in 1683 of the small-pox, and was buried at the little town of Aire and not Arras; in which Father Griffet was mistaken, but in which to be sure there is no great harm.—Others have imagined, that it was the duke of Monmouth, who was beheaded publicly in London in the year 1685. But for this he must have risen again from the dead, and he must have changed the order of time, and placed the year 1662 in the room of the year 1685. King James, who never forgave any one, and who on that account deserved all that happened to him, must have pardoned the duke of Monmouth, and got another to die in his stead, who perfectly resembled him. This Sofia must first have been found, and then he must have had the goodness to let his head be cut off in public, to save the duke of Monmouth. It was necessary that all England should be mistaken; and that King James should beg of Louis XIV. to be so obliging as to be his gaoler; that Louis XIV. after having shown this trifling piece of civility to King James, should not have been wanting in the same attention to his friend King William and to Queen Anne (with both of whom he was engaged in war), and to please them, retained the dignity of gaoler, with which James had honoured him.

"All these illusions being dissipated, it then remains to know who this prisoner was, and at what age he died. It is clear, that if he was not permitted to cross the court of the Bastille, or to speak to his physician, except covered with a masque, it must have been from the apprehension that his features and countenance

* *Traité de la Verité de l'Histoire*, p. 318. n.

Masque.

nance might have discovered some resemblance. He could show his tongue, but not his face. He said himself to the apothecary of the Bastille, a few days before his death, that he believed he was about 60. Mr Marsoban, who was son-in-law to this apothecary, and surgeon to the marshal de Richlieu, and afterwards to the regent duke of Orleans, told me this frequently. Why give him an *ITALIAN* name!—They always called him *Marchiali*. He who writes this article perhaps knows more than Father Griffet, but he will say nothing farther."

This opinion has been lately resumed, illustrated, and enforced, by M. de Saint Mihiel, in a work intitled *Le Vritable Homme*, &c. "The real Man with the Iron Masque." The author, in support of his idea, attempts to prove that Anne of Austria and Cardinal Mazarine were married. This, says he, the duchess of Orleans assures us of in three of her letters. In the first, dated Sept. 13. 1713, she expresses herself as follows: "Old Beauvais, who was first lady of the bed-chamber to the queen-dowager, was acquainted with the secret of the ridiculous marriage; this rendered it necessary for the queen to do every thing that her confidant wished; and this circumstance has given rise in this country to an extension of the rights of first ladies of the bedchamber." In the second of these letters, dated Nov. 2. 1717, she says, "The queen-mother, widow of Louis XIII. did worse than love Cardinal Mazarine; he married him, for he was not a priest: he was not even in orders; and who could have hindered her? He was most horribly tired of the good queen-mother, and lived on very bad terms with her, which is the reward that people deserve for entering into such marriages." In her third letter, dated July 2. 1719, speaking of the queen, the duchess says, "She was perfectly easy respecting Cardinal Mazarine; he was not a priest, and therefore nothing could prevent their being married. The secret passage through which the Cardinal went every evening to the queen's apartment is still to be seen at the Palais-Royal." Among other proofs besides the above, which M. de St Mihiel brings to substantiate this marriage, he observes, that Mazarine held all councils of state in his apartment whilst he was shaving or dressing; that he never permitted any person to sit down in his presence, not even the chancellor nor marshal de Villeroi; and that while they were deliberating with him on state affairs he would be often playing with his monkey or linnet. What man (continues the author) would have subjected to such humiliations a chancellor, who holds the first office in the kingdom since that of constable has been suppressed, and a marshal who was governor to the king, had he not been in reality a sovereign himself, in virtue of his being husband to the queen-regent? He therefore concludes, that the man with the iron masque was son to Anne of Austria and Cardinal Mazarine; and endeavours to justify this assertion by a variety of conjectural proofs. Of some of these we shall give a short sketch:

1. No prince, or person of any consideration, after the year 1644, at which time the man with the iron masque was born, until the time when his existence was known, disappeared in France. This personage, therefore, was not a prince or great lord of France known at that time.

Masque.

2. The man with the iron masque was not a foreigner; for foreigners, even of the highest distinction, did not at that period study the French language in such a manner as to attain so great perfection in it as to pass for Frenchmen. If this prisoner had spoken with the least foreign accent, the officers, physicians, surgeons, apothecaries, confessors, and others employed in the prisons where he was, and especially the prisoners with whom he conversed at St Margaret, would not have failed to discover it. From all this M. de St Mihiel infers that he must have been a Frenchman.

3. The existence of the man with the iron masque has been known for upwards of 90 years. Had any person of high rank disappeared at an anterior period, his friends, relations, or acquaintances, would not have failed to claim him, or at least to suppose that he was the man concealed by this masque. But no one disappeared, nor was any one claimed: the man with the iron masque was therefore a person unknown.

4. This man was not torn away from society on account of any criminal action; for when he was arrested, it was foreseen that he would cause much embarrassment, and occasion great expences. He was therefore not a criminal, else means would have been pursued to get rid of him; and consequently all the importance of his being concealed was attached solely to his person.

5. This stranger must have been a person of very high birth; for the governor of the prison St Mars behaved always to him with the greatest respect.

6. Louis XIII. played on the guitar; Louis XIV. did the same in a very masterly manner; and the man with the iron masque played also on that instrument: which gives us reason to believe that his education was directed by the same persons who had preided over that of Louis XIV. and who appear to have been the particular choice of Anne of Austria.

7. This stranger died on the 19th of November 1703; and a few days before his death, he told the apothecary of the Bastille, that he believed he was about 60 years of age. Supposing that he was then 59 and a half, he must have been born towards the end of May 1644; and if he was 60 wanting three months, he must have been born in the end of August, or the beginning of September, of the same year; a period when the royal authority was in the hands of Anne of Austria, but in reality exercised more by Mazarine than by her. "I have already proved (continues the author), that from the first day of the regency of Anne of Austria, the greatest friendship, and even intimacy, subsisted between this prince and the cardinal; that these sentiments were changed into a mutual love; and that they were afterwards united by the bonds of marriage. They might, therefore, well have a son about the month of September 1644, as Louis XIII. had been then dead more than 15 months, having died on the 15th of May the year preceding. But nothing of what I have related, or of what has been written, and acknowledged as fact, respecting the man with the iron mask, can be applied, except to a son of Mazarine and Anne of Austria. The man with the iron mask was indebted, therefore, for his existence to cardinal Mazarine, and the regent widow of Louis XIII."—To account for the

the manner in which the queen was able to conceal her pregnancy and delivery, Madame de Motteville is quoted; who relates, under the year 1644, that Anne of Austria quitted the Louvre, because her apartments there displeased her: that she went to reside at the Palais-Royal, which Richlieu, when he died, bequeathed to the deceased king: that when she first occupied this lodging, *she was dreadfully afflicted with the jaundice*: that the physicians ascribed this disorder to her dejection and application to business, which gave her much embarrassment: but that being cured of her melancholy, as well as of her malady, she resolved to think only of enjoying tranquillity; which she did, by communicating to her minister the burden of public affairs. On this quotation, M. de St Mihiel asks, "Is it not very singular, that the queen, who, during the 29 years of her former wedded state, had always resided in the Louvre, especially from 1626, when Louis XIII. ceased to cohabit with her, until their re-union, which took place in the beginning of December 1637, should have quitted it precisely in 1644, because she was displeased with her apartments? How happened it that her apartments displeased her this year, and neither sooner nor later? She might undoubtedly have had any kind of furniture there which she desired, and every alteration made according to her wishes, as she was then absolute mistress: but the cause of her determination is plain; the apartments of the Palais-Royal, which front a garden, were much more convenient for her to be delivered in secret."

8. As it is necessary that some name should be given to every man, in order to distinguish him from another, that of *Marchiali* was given to the man with the iron mask: a name which evidently shows, that it had been invented by an Italian. [Cardinal Mazarine was a native of Piccina in the Abruzzo.]

9. Anne of Austria was remarkably delicate respecting every thing that touched her person. It was with great difficulty that cambric could be found fine enough to make shifts and sheets for her. Cardinal Mazarine once rallying her on this subject, said, *That if she should be damned, her punishment in hell would be to sleep in Holland sheets.* The predominant taste of the man with the iron masque, was to have lace and linen of the most extraordinary fineness. "Who (says the author) does not perceive, in this similarity of tastes, the maternal tenderness of Anne of Austria, who would have thought her son a great sufferer had he not been indulged with fine linen?"

"Louis XIII. (continues M. de St Mihiel) was a husband of a gloomy disposition, and an enemy to pleasure: while the queen, on the contrary, was fond of social life; and introduced at the court of France, especially after she became free, that ease and politeness which distinguished it under Louis XIV. from all the other courts of Europe. Louis XIII. had also a disagreeable countenance, and a breath so offensive, that it was a punishment for Richlieu to remain near him. It is clear, therefore, that she could not be much pleased with such a husband. When she became regent of the kingdom by the king's death, which happened on the 14th of May 1643, as she had not enjoyed that happiness which arises from a close union of hearts, it will not appear extraordinary

that she should indulge the affection she entertained for cardinal Mazarine, and that she should marry him. Every circumstance that could tend to favour such a marriage will be found united in her situation. She was at a distance from her family; absolute mistress of all her actions; and had, besides, a heart formed for love. Mazarine, though a cardinal, had never entered into orders; he gave out that he was descended from a great family; he was handsome and well made; he was of a mild, insinuating disposition, and remarkably engaging in conversation; and his office, as prime minister, afforded him every opportunity of visiting and conversing with the queen whenever he thought proper. Is it, therefore, so very astonishing, that, with so many advantages, he was able to captivate the queen so far as to induce her to marry him? Such a marriage was not, indeed, according to the usual course of things. Yet it was not without many precedents, particularly among sovereigns of the other sex, who had given their hands to persons of inferior rank. Thus Christian IV. of Denmark espoused Christina Monck; Frederick IV. espoused Mademoiselle Reventlau; James II. heir to the throne of England, married the daughter of a counsellor; Peter the Great raised to the throne Catharine I. the daughter of a poor villager, yet perhaps the most accomplished woman at that time between the Vistula and the pole; and Louis XIV. espoused the widow of a poet, but a woman possessed of the most extraordinary merit. As the women, however, are not forgiven so readily as the men for entering into such marriages, Anne of Austria kept hers a secret from this motive, and because she would have been in danger of losing the regency of the kingdom had it been known."

The reasoning of M. de St Mihiel is both ingenious and plausible; though the probability of the account is somewhat diminished by considering what must have been the queen's age at this period, after she had been Louis's wife for 29 years before his death.—The account immediately preceding, without this objection, seems abundantly credible. But whether, upon the whole, either of them can be received as decisive, or whether the mystery of the iron mask remains still to be unravelled, we must leave to the reader to determine.

MASQUE, in architecture, is applied to certain pieces of sculpture, representing some hideous forms, grotesque, or satyr's faces, &c. used to fill up and adorn vacant places, as in friezes, the panels of doors, keys of arches, &c. but particularly in grottos.

MASQUERADE, or MASCARADE, an assembly of persons masked or disguised, meeting to dance and divert themselves. This was much in use with us, and has been long a very common practice abroad, especially in carnival time.

The word comes from the Italian *mascarata*, and that from the Arabic *maskara*, which signifies "rillery, buffoonery." Granacci, who died in 1543, is said to have been the first inventor of masquerades.

MASRAKITHA, a pneumatic instrument of music among the ancient Hebrews, composed of pipes of various sizes, fitted into a kind of wooden chest, open at the top, and stopped at the bottom with wood covered with a skin. Wind was conveyed to it from the

Maf.

the lips, by means of a pipe fixed to the chest: the pipes were of lengths musically proportioned to each other, and the melody was varied at pleasure, by stopping and unstopping with the fingers the apertures at the upper extremity. See Plate CCLXXIX.

MASS, in mechanics, the matter of any body cohering with it, *i. e.* moving and gravitating along with it. In which sense, *mas* is distinguished from bulk, or volume, which is the expansion of a body in length, breadth, and thickness.

The mafs of any body is rightly estimated by its weight. And the masses of two bodies of the same weight are in a reciprocal ratio of their bulks.

MASS, *Missa*, in the church of Rome, the office or prayers used at the celebration of the eucharist; or in other words consecrating the bread and wine into the body and blood of Christ, and offering them to transubstantiate as an expiatory sacrifice for the quick and the dead.

As the mafs is in general believed to be a representation of the passion of our blessed Saviour, to every action of the priest, and every particular part of the service, is supposed to allude to the particular circumstances of his passion and death.

Nicod, after Baronius, observes that the word comes from the Hebrew *missach*, (*oblatum*); or from the Latin *missa missurum*; as common in the former times, the catechumens and excommunicated were sent out of the church, when the deacons said, *Ite, missa est*, after sermon and reading of the epistle and gospel; they not being allowed to assist at the consecration. Menage derives the word from *missio*, "dismissing;" Others from *missa*, "missing, sending;" because in the mafs, the prayers of men on earth are sent up to heaven.

The general division of masses consists in high and low. The first is that sung by the choristers, and celebrated with the assistance of a deacon and sub-deacon; low masses are those in which the prayers are barely rehearsed without singing.

There are a great number of different or occasional masses in the Romish church, many of which have nothing peculiar but the name: such are the masses of the saints; that of St Mary of the snow, celebrated on the fifth of August; that of St Margaret, patroness of lying-in women; that of the feast of St John the Baptist, at which are said three masses; that of the Innocents, at which the gloria in excelsis and the hallelujah are omitted, and it being a day of mourning, the altar is of a violet-colour. As to ordinary masses, some are said for the dead, and, as is supposed, contribute to fetch the soul out of purgatory: at these masses the altar is put in mourning, and the only decorations are a cross in the middle of six yellow wax-lights; the dress of the celebrant, and the very mass-book, are black; many parts of the office are omitted, and the people are dismissed without the benediction. If the mafs be said for a person distinguished by his rank or virtues, it is followed with a funeral oration; they erect a *chapelle ardente*, that is, a representation of the deceased with branches and tapers of yellow wax, either in the middle of the church, or near the deceased's tomb, where the priest pronounces a solemn absolution of the deceased. There are likewise private masses said for stolen or strayed goods or cattle,

VOL. X. Part II.

for health, for travellers, &c. which go under the name of *votive masses*. There is still a further distinction of masses denominated from the countries in which they were used; thus the Gothic mafs, or *missa mosarabum*, is that used among the Goths when they were masters of Spain, and which is still kept up at Toledo and Salamanca; the Ambrosian mafs is that composed by St Ambrose, and used only at Milan, of which city he was bishop; the Gallic mafs, used by the ancient Gauls; and the Roman mafs, used by almost all the churches in the Romish communion.

Mass of the Pre-sanctified, (*missa pre-sanctificatorum*), is a mafs peculiar to the Greek church, in which there is no consecration of the elements; but after singing some hymns, they receive the bread and wine which was before consecrated. This mafs is performed all Lent, except on Saturdays, Sundays, and the annunciation. The priest counts upon his fingers the days of the ensuing week on which it is to be celebrated, and cuts off as many pieces of bread at the altar as he is to say masses; and after having consecrated them, steep them in wine, and then puts them in a box; out of which, upon every occasion, he takes some of it with a spoon, and putting it on a dish sets it upon the altar.

MASSA, a town of Italy, in the kingdom of Naples, and in the Terra di Lavoro, with a bishop's see; seated on a mountain near the sea, in E. Long. 10. 0. N. Lat. 43. 5.

MASSA, an ancient, populous, and handsome town of Italy, and capital of a small territory of the same name, with the title of a principality, and a strong castle. It is famous for its quarries of fine marble, and is situated in E. Long. 14. 23. N. Lat. 40. 40.

MASSACHUSETTS COLONY, the principal subdivision of New England, having Hampshire on the north, the Atlantic ocean on the east and south, and Connecticut and New York on the west. It is about 100 miles long, and 40 broad. See *New ENGLAND*.

MASSACRE, a term used to signify the sudden and promiscuous butchery of a multitude. The most atrocious example of this kind upon record is that called the *Parisian MASSACRE*, or *Massacre of St Bartholomew's Day*. The Parisian massacre was carried on with such detestable perfidy, and executed with such a bloody cruelty, as would surpass all belief, were it not attested by the most undeniable evidence. In the year 1572, in the reign of Charles IX. many of the principal protestants were invited to Paris, under a solemn oath of safety, upon occasion of the marriage of the king of Navarre with the French king's sister, viz. the king of Navarre's mother, Coligni admiral of France, with other nobles. The queen-dowager of Navarre, a zealous protestant, was poisoned by a pair of gloves before the marriage was solemnized; and on the 24th of August 1572, being Bartholomew's day, about day-break, upon the toll of the bell of the church of St Germain, the butchery began. The admiral was basely murdered in his own house; and then thrown out of the window, to gratify the malice of the duke of Guise: his head was afterwards cut off, and sent to the king and queen-mother; and his body, after a thousand indignities offered to it, hung up by the feet on a gibbet. After this,

4 L

the

Maf

H
Massacre.

Massacre. the murderers ravaged the whole city of Paris, and butchered in three days above ten thousand lords, gentlemen, prebends, and people of all ranks. An horrible scene of things, says Thuanus, when the very streets and passages resounded with the noise of those that met together for murder and plunder; the groans of those who were dying, and the shrieks of such as were just going to be butchered, were every where heard; the bodies of the slain thrown out of the windows; the courts and chambers of the houses filled with them; the dead bodies of others dragged through the streets, their blood running down the channels in such plenty, that torrents seemed to empty themselves in the neighbouring river: and, in a word, an innumerable multitude of men, women with child, maidens, and children, were all involved in one common destruction; and the gates and entrances of the king's palace all besmeared with their blood.

From the city of Paris the massacre spread almost throughout the whole kingdom. In the city of Meaux they threw above two hundred into jail; and after they had ravished and killed a great number of women, and plundered the houses of the protestants, they executed their fury on those they had imprisoned, and calling them out one by one, they were killed, as Thuanus expresses, like sheep in a market; the bodies of some were flung into ditches, and of others into the river Maine. In Orleans they murdered above five hundred men, women, and children, and enriched themselves with their spoil. The same cruelties were practised at Angers, Troyes, Bourges, La-Charité, and especially at Lyons, where they inhumanly destroyed above eight hundred protestants; children hanging on their parents necks; parents embracing their children; putting ropes about the necks of some, dragging them through the streets, and throwing them, mangled, torn, and half-dead, into the river.

It would be endless to mention the butcheries committed at Valence, Romaine, Rouen, &c. We shall, therefore, only add, that, according to Thuanus, above thirty thousand protestants were destroyed in this massacre, or, as others with greater probability affirm, above one hundred thousand.

Thuanus himself calls this a most detestable villainy; and, in abhorrence of St Bartholomew's days, used to repeat these words of P. Statius, *Silv. v. iiii. ver. 88. &c.*

*Excidit illa dies avo, ne postera creant
Secula. Nos certe tacemus, et obruta multa
Nocte tegi propriæ potius crimina gentis.*

In the words of Job, chap. iii. ver. 3. &c. "Let that day perish; and let it not be joined unto the days of the year. Let darkness and the shadow of death stain it," &c. And yet, as though this had been the most heroic transaction, and could have procured immortal glory to the authors of it, medals were struck at Paris in honour of it.

But how was the news of this butchery received at Rome, that faithful city, that holy mother of churches! How did the vicar of Christ, the successor of Peter, and the father of the Christian world, relish it? Let Thuanus tell the horrid truth. When the news, says he, came to Rome, it was wonderful to see how they exulted for joy. On the 6th of September, when the letters of the pope's legate were read in the assembly

of the cardinals, by which he assured the Pope that all was transacted by the express will and command of the king, it was immediately decreed that the pope should march with his cardinals to the church of St Mark, and in the most solemn manner give thanks to God for so great a blessing conferred on the see of Rome and the Christian world; and that on the Monday after, solemn mass should be celebrated in the church of Minerva; at which the pope, Greg. XIII. and cardinals were present; and that a jubilee should be published throughout the whole Christian world, and the cause of it declared to be, to return thanks to God for the extirpation of the enemies of the truth and church in France. In the evening the cannon of St Angelo were fired, to testify the public joy; the whole city illuminated with bonfires; and no one sign of rejoicing omitted that was usually made for the greatest victories obtained in favour of the Roman church.

MASSAGETAE, an ancient people about whose seat there is as much doubt as about that of the Amazons: Tibullus and Ammian place them near Albania, beyond the Araxes, which sometimes denotes the Oxus; it is probable they dwelt to the east of Sogdiana, (Dionysius Periegetes, Herodotus, Arrian).

MASSALIANS, a set of enthusiasts who sprang up about the year 361, in the reign of the emperor Constantius, who maintained that men have two souls, a celestial and a diabolical, and that the latter is driven out by prayer.

MASSANIELLO, see *History of Naples*.

MASSETER, in anatomy. See there, (*Table of the Muscles*).

MASSICOT, see MASTICOT.

MASSIEU (William), a learned French writer, member of the academy of belles lettres, and of the French academy, was born at Caen in Normandy in 1665, and completed his studies at Paris, when he entered amongst the Jesuits; but afterwards left them, that he might follow his inclination to polite literature with the greater freedom. In 1710 he was made Greek professor in the royal college; and enjoyed that post till his death, which happened at Paris in 1722. He wrote, 1. Several curious dissertations in the memoirs of the academy of inscriptions. 2. A history of the French poetry, in 12mo, &c.

MASSILIA, (anc. geog.) a town of Gallia Narbonensis, a colony of Phœceans, from Phœcæa, a city of Ionia, and in confederacy with the Romans; universally celebrated, not only for its port, commerce, and strength, but especially for its politeness of manners and for its learning. According to Strabo, it was the school for barbarians, who were excited by its means to a fondness for Greek literature, so that even their public and private transactions were all executed in that language. Strabo adds, "At this day the noblest Romans repair thither for study rather than to Athens." Now MARSEILLES, a city and port-town of Provence.

MASSILLON (Jean Baptiste), son of a notary at Hieres in Provence, was born in 1663, and entered into the congregation of the oratory in 1681. He gained the affections of every person in the towns to which he was sent, by the charms of his genius, the liveliness of his character, and by a fund of the most delicate

Massagetae

Massilion.

Maffillon. delicate and affecting politeness. His first attempts in the art of eloquence were made at Vienna, while he was professor of theology. His funeral oration on Henry de Villars, archbishop of that city, received universal approbation. This success induced Father de la Tour, who was at that time general of the congregation, to call him to Paris. After he had been there for some time, he was asked what he thought of the preachers who made a figure on that great theatre?—"I find them possessed of great genius and abilities (answered he); but if I preach, I will not preach like them." He in fact kept his word, and struck out a new path in this great field of eloquence. P. Bourdaloue was excepted from the number of those whom he proposed not to imitate. If he did not take him for a model in every thing, the reason was, that his genius led him to a different species of eloquence.—His manner of composing, therefore, was peculiar to himself; and, in the opinion of men of taste and judgment, was superior to that of Bourdaloue. The affecting and natural simplicity of the father of the oratory, (said a great man), appear fitter to bring home the truths of Christianity to the heart than all the dialectics of the Jesuit. We must seek for the logic of the gospel in our own breasts; and the most powerful reasonings on the indispensable duty of relieving the distressed, will make no impression on that man who has beheld without concern the sufferings of his brother. If logic is necessary, it is only in matters of opinion; and these are fitter for the press than for the pulpit, which ought not to be the theatre of learned discussions. The truth of these reflections was clearly perceived when he appeared at court. Upon preaching his first advent sermon at Versailles, he received this eulogium from the mouth of Louis XIV. "Father, when I hear others preach, I am very well pleased with them; but whenever I hear you, I am dissatisfied with myself." The first time he preached his famous sermon on the small number of the elect, the whole audience were, at a certain place of it, seized with a sudden and violent emotion, and almost every person half rose from his seat by a kind of involuntary movement. The murmur of acclamation and surprise was so great, that it threw the orator into confusion; but this only heightened the impression of that pathetic discourse. What was most surprising in Maffillon, was his descriptions of the world, which were so sublime, so delicate, and so striking in the resemblance. When he was asked whence a man, like him, whose life was dedicated to retirement, could borrow them? he answered, "From the human heart; however little we examine it, we will find in it the seeds of every passion. When I compose a sermon (added he), I imagine myself consulted upon some doubtful piece of business. I give my whole application to determine the person who has recourse to me, to act the good and proper part. I exhort him, I urge him, and I leave him not till he has yielded to my persuasions." His declamation did not fail to be accompanied with success. "We think we see him in our pulpits (say those who had the pleasure of hearing him), with the simple air, the modest carriage, the down-cast and humble looks, the easy gesture, the affecting tone, and the countenance of a man deeply penetrated with his subject, conveying the clearest information to the

understanding, and raising the most tender emotions in the heart." Baron, the famous comedian, having met him one day in a house which was open for the reception of men of letters, paid him this compliment: "Continue to deliver as you do. Your manner is peculiar to yourself; leave the observance of rules to others." When this famous actor came from hearing one of his sermons, truth drew from him the following confession, which is so humiliating to his profession: "Friend (said he to one of his companions who accompanied him), here is an orator; we are only actors."

In 1704 Maffillon made his second appearance at court, and displayed still more eloquence than before. Louis XIV. after expressing his satisfaction to him, added, in the most gracious tone of voice, *Et je veux, mon pere, vous entendre tous les deux ans.* These flattering encomiums did not lessen his modesty. When one of his fellows was congratulating him upon his preaching admirably, according to custom, "Oh! give over, Father (replied he), the devil has told me so already, much more eloquently than you." The duties of his office did not prevent him from enjoying society; and in the country he forgot that he was a preacher, but always without trespassing against decency. One day when he was at the house of M. de Crozat, the latter said to him, "Father, your doctrine terrifies me, but I am encouraged by your life." He was chosen, on account of his philosophical and conciliatory disposition of mind, to reconcile the cardinal de Noailles with the Jesuits. All he gained by his attempts was the displeasure of both parties; and he found that it was easier to convert sinners than to reconcile theologians. In 1717, the regent, personally acquainted with his merit, appointed him to the bishopric of Clermont. The next year, being destined to preach before Louis XV. who was only nine years of age, he composed in six weeks those discourses which are so well known by the name of *Petit Carême*. These are the chief d'œuvre of this orator, and indeed of the oratorical art. They ought continually to be read by preachers as models for the formation of their taste, and by princes as lessons of humanity.

Maffillon was admitted into the French academy a year afterwards, in 1719. The abbey of Savigny becoming vacant, the cardinal du Bois, to whom he had been weak enough to give an attestation for being a priest, procured it for him. The funeral oration of the dukes of Orleans, in 1723, was the last discourse he pronounced in Paris. He never afterwards left his diocese, where his gentleness, politeness, and kindness, had gained him the affection of all who knew him. He reduced the exorbitant rights of the episcopal roll to moderate sums. In two years, he caused 22,000 livres to be privately conveyed to the Hotel-Dieu of Clermont. His peaceable disposition was never more displayed than while he was a bishop. He took great pleasure in collecting the fathers of the oratory and the Jesuits at his country-house, and in making them join in some diversion. He died on the 28th of September 1743, at the age of 70. His name has become that of eloquence itself. Nobody ever knew better how to touch the passions. Preferring sentiment to every thing else, he communicated to the soul that lively and salutary emotion which ex-

Maffillon.

cites in us the love of virtue. What pathetic eloquence did his discourses display! what knowledge of the human heart! what constant disclosing of a mind deeply affected with his subject! what strain of truth, philosophy, and humanity! what imagination, at once the most lively, and guided by the soundest judgment! Just and delicate thoughts; splendid and lofty ideas; elegant, well chosen, sublime, and harmonious expressions; brilliant and natural images; true and lively colouring; a clear, neat, swelling, and copious style, equally suited to the capacity of the multitude, and fitted to please the man of genius, the philosopher, and the courtier, form the character of Maffillon's eloquence, especially in his *Petit Carême*. He could at once think, describe, and feel. It has been justly observed concerning him, that he was to Bourdaloue what Racine was to Corneille. To give the finishing stroke to his eulogium, Of all the French orators, he is the most esteemed by foreigners.

An excellent edition of Maffillon's works was published by his nephew at Paris in 1745 and 1746, in 14 vols. large 12mo, and 12 vols. of a small size.—Among them we find, 1. Complete sets of Sermons for Advent and Lent. It is particularly in his moral discourses, such as are almost all those of his sermons for Advent and Lent, that Maffillon's genius appears. He excels, says M. d'Alembert, in that species of eloquence, which alone may be preferred to all others, which goes directly to the heart, and which agitates without wounding the soul. He searches the inmost recesses of the heart, and lays open the secret workings of the passions, with so delicate and tender a hand, that we are hurried along rather than overcome. His diction, which is always easy, elegant, and pure, every where partakes of that noble simplicity, without which there can be neither good taste nor true eloquence; and this simplicity is, in Maffillon, joined to the most attractive and the sweetest harmony, from which it likewise borrows new graces. In short, to complete the charm produced by this enchanting style, we perceive that these beauties are perfectly natural; that they flow easily from this source, and that they have occasioned no labour to the composer. There even occur sometimes in the expressions, in the turns, or in the affecting melody of his style, instances of negligence which may be called happy, because they completely remove every appearance of labour. By thus abandoning himself to the natural current of thought and expression, Maffillon gained as many friends as hearers. He knew, that the more anxious an orator appears to raise admiration, he will find those who hear him the less disposed to bestow it. 2. Several Funeral Orations, Discourses, and Panegyrics, which had never been published. 3. Ten discourses, known by the name of *Petit Carême*. 4. The *Conferencées ecclésiastiques*, which he delivered in the seminary of St Magloire upon his arrival at Paris; those which he delivered to the curates of his diocese; and the discourses which he pronounced at the head of the synods which he assembled every year. 5. Paraphrases on several of the Psalms. The illustrious author of these excellent tracts wished that they had introduced into France a practice which prevails in England, of reading sermons instead of preaching them from

mory; a custom which is very convenient, but by which all the warmth and fervour of eloquence are lost. He, as well as two others of his brethren, had stood short in the pulpit exactly on the same day.—They were all to preach at different hours on Good-Friday, and they went to hear one another in succession. The memory of the first failed, which so terrified the other two, that they experienced the same fate. When our illustrious orator was asked, what was his best sermon? he answered, "That which I am most master of." The same reply is ascribed to Bourdaloue. The celebrated P. la Rue was of the opinion of Maffillon, that getting by heart was a slavery which deprived the pulpit of a great many orators, and which was attended with many inconveniences to those who dedicated themselves to it. The Abbé de la Porte has collected into 1 vol. 12mo the most striking ideas, and the most sublime strokes, which occur in the works of the celebrated bishop of Clermont. This collection, which is made with great judgment, appeared at Paris in 1748, 12mo, and forms the 15th volume of the large edition in 12mo, and the 13th of the small in 12mo. It is entitled, *Pensées sur différents sujets de morale et de piété, tirées, &c.*

MASSINGER (Philip), an English dramatic poet, was born at Salisbury about the year 1581, and was educated at Oxford. He left the university without taking any degree; and went to London to improve his poetical genius by polite conversation. There he wrote many tragedies and comedies, which were received with vast applause; and were greatly admired for the economy of the plots and the purity of the style. He was at the same time a person of the most consummate modesty; which rendered him extremely beloved by the poets of his time, particularly by Fletcher, Middleton, Rowley, Field, and Decker, who thought it an honour to write in conjunction with him. He was as remarkable for his abilities as his modesty. He died suddenly at his house on the Bank-side in Southwark, near the play-house; and was interred in St Saviour's church-yard, in the same grave with Mr Fletcher the poet.

MASSIVE, among builders, an epithet given to whatever is too heavy and solid: thus a massive column is one too short and thick for the order whose capital it bears; and a massive wall is one whose openings or lights are too small in proportion.

MASSON (Papirius), a French writer, was the son of a rich merchant, and born in the territory of Forez, May 1541. After studying the belles lettres and philosophy, and travelling to different places, he came to Paris, where he was made librarian to the chancellor of the duke of Anjou, in which place he continued ten years. In 1576, he was made an advocate of parliament; yet never pleaded but one cause, which, however, he gained with universal applause.—When the troubles of France were at an end, he married the sister of a counsellor in parliament, with whom he lived thirty-four years, but had no issue by her.—The infirmities of age attacked him some time before his death, which happened Jan. 9, 1611. He wrote four books of French annals in Latin, first printed at Paris 1577, and afterwards in 1598, 4to. The second edition, more enlarged than the first, deduces

things.

Maffon,
Maffuah.

things from Pharamond to Henry II. Maffon considered this as his principal performance; yet he is now chiefly known by his *Elogia virorum clarissimorum*, although he published several other works.

MASSON (John), a reformed minister in Holland some years ago. He was originally of France, but fled into England to enjoy that liberty in religion which his country refused him. He wrote, 1. *Histoire critique de la république des lettres*, from 1712 to 1717, in 15 vols. 12mo. 2. *Vite Horatii, Ovidii, et Plinii junioris*, 3 vols small 8vo, and printed abroad, though dedicated to Englishmen of rank: the first at Leyden, 1708, to lord Harvey; the second at Amsterdam, 1708, to Sir Justinian Isham; the third at Amsterdam, 1709, to the bishop of Worcester. These lives are drawn up in a chronological order, very learnedly and very critically; and serve to illustrate the history, not only of those particular persons, but of the times also in which they lived. 3. *Histoire de Pierre Bayle et de ses ouvrages*; Amsterdam, 1716, in 12mo. This at least is supposed to be his, though at first it was given to M. la Monnoye.

MASSON (Anthony), an eminent French engraver, who flourished towards the conclusion of the last century, and resided chiefly at Paris. It appears that he sometimes amused himself with painting portraits from the life, some of which he also engraved. We have no account of the life of this extraordinary artist; nor are we even informed from what master he learned the principles of engraving. He worked entirely with the graver, and handled that instrument with altonifying facility. He seems to have had no kind of rule to direct him with respect to the turning of the strokes; but twitted and tired them about, without the least regard to the different forms he intended to express, making them entirely subservient to his own caprice. Yet the effect he has produced in this singular manner (Mr Strutt observes), is not only far superior to what one could have supposed, but is often very picturesque and beautiful. It was not in historical engraving that his greatest strength consisted. He could not draw the naked parts of the human figure so correctly as was necessary; but where the subject required the figures to be clothed, he succeeded in a wonderful manner. Among the most esteemed works by this admirable artist, may be reckoned the following: The assumption of the Virgin, a large upright plate from Rubens; a holy family, a middling-sized plate, lengthwise, from N. Mignard; Christ with the pilgrims at Emaus, a large plate, lengthwise, from Titian, the original picture of which is in the cabinet of the king of France. This admirable print is commonly known by the name of the *table-cloth*; for the cloth, with which the table is covered, is executed in a very singular style. Also the following portraits, among others: The comte de Harcourt, a large upright plate, reckoned a masterpiece in this class of subjects; Guillaume de Brisiac, secretary to the queen of France; a middling-sized upright plate: usually known in England by the name of the *Grey-headed Man*, because the hair in this print is so finely executed.

MASSUAH, a small island in the Red Sea, near the coast of Abyssinia, about three quarters of a mile long, and half as broad, one-third of which is occu-

Maffuah.

piated by houses, another by cisterns for receiving rain-water, and one reserved for a burial place. It has an excellent harbour, with water sufficiently deep for ships of any size to the very edge of the island; and so well secured, that they may ride in safety, let the wind blow from what quarter or with what degree of strength it will. By the ancients it was called *Sebafium Ors*, and was formerly a place of great consequence on account of its harbour, from whence a very extensive commerce was carried on, and possessed a share of the Indian trade in common with other ports of the Red Sea near the Indian Ocean.—A very considerable quantity of valuable goods was also brought thither from the tract of mountainous country behind it, which in all ages has been accounted very un hospitable, and almost inaccessible to strangers. The principal articles of exportation were gold, ivory, elephants, and buffaloes hides; but above all slaves, who, on account of their personal qualifications, were more esteemed than those from any other quarter.—Pearls of a considerable size, and of a fine water, are likewise found along the coast; from the abundance of all which valuable commodities, the great defect, a want of water, was forgot, and the inhabitants cheerfully submitted to such a great inconvenience. The island of Maffuah fell under the power of the Turks in the time of the emperor Selim, soon after the conquest of Arabia Felix by Sinan Pasha, and was for some time governed by an officer from Constantinople. From thence the conquest of Abyssinia was for some time attempted, but always without success. Hence it began to lose its value as a garrison for troops, as it had done in the commercial way after the discovery of the passage to India by the Cape of Good Hope.—Being thus deprived of its importance in every respect, the Turks no longer thought it worth while to send a pasha thither as formerly, but conferred the government upon the chief of a tribe of Mahometans named *Belawie*, who inhabit the coasts of the Red Sea under the mountains of Habab, in the latitude of about 14° north. On this officer they conferred the title of *Naybe*; and on the removal of the pasha, he remained in fact master of the place, though, to save appearances, he pretended to hold it from the Ottoman Porte, by a firman from the Grand Signior for that purpose, and the payment of an annual tribute.

The Turks had originally put into the town of Maffuah a garrison of Janizaries; who, being left there on the withdrawing of the pasha, and intermarrying with the natives, soon became entirely subjected to the Naybe's influence. The latter, finding himself at a great distance from his protectors the Turks, whose garrisons were every where falling into decay, and that in consequence of this he was entirely in the power of the emperor of Abyssinia, began to think of taking some method of securing himself on that side. Accordingly it was agreed that one half of the customs should be paid to the Abyssinian monarch; who in return was to allow him to enjoy his government unmolested. Having thus secured the friendship of the emperor of Abyssinia, the Naybe began gradually to withdraw the tribute he had been accustomed to pay to the pasha of Jidda, to whose government Maffuah had been assigned; and at last to pay a little regard to the government of Abyssinia; and in this state of

Maſſuah.

independence he was when Mr Bruce arrived there in 1760 on his way to Abyſſinia. This gentleman found both the prince and his people extremely unhoſpitable and treacherous; ſo that he underwent a variety of dangers during his reſidence there, nor was it without great difficulty that he could get away from thence at laſt.

The iſland of Maſſuah, as we have ſaid, is entirely deſtitute of water; nor can it be ſupplied with provisions of any kind but from the mountainous country of Abyſſinia on the continent. Arkeeko, a large town in the bottom of the bay, has water, but is in the ſame predicament with regard to provisions; for the adjacent tract of flat land, named *Sambar*, is a perfect deſart, inhabited only from the month of November to April by ſome wandering tribes, who carry all their cattle to the Abyſſinian ſide of the mountains when the rains fall there. Being thus in the territories of the Abyſſinians, it is in the power of the emperor of that country, or of his officer the Bahama-gaſſi, to ſtarve Maſſuah and Arkeeko, by prohibiting the paſſage of any provisions from the Abyſſinian ſide of the mountains.

The houſes of Maſſuah are generally conſtructed of long poles and bent graſs, as is uſual with other towns of Arabia: only about 20 are of ſtone, and fix or eight of theſe two ſtories high. The ſtones with which they are built have been drawn out of the ſea; and in them the bed of that curious muſcle found embodied in the ſolid rock at Mahon is frequently to be ſeen. Theſe are called *dattoli da mare*, or ſea-dates: but our author never ſaw any of the fiſh themſelves, though he has no doubt that they may be met with in the rocky iſlands of Maſſuah if they would take the trouble of breaking the rocks for them. All the neceſſaries of life are very dear in this place; and their quality is alſo very indifferent, owing to the diſtance from whence they muſt be brought, and the danger of carrying them through the deſart of Sambar, as well as to the extortions of the Naybe himſelf, who, under the name of *cuiſtoms*, takes whatever part of the goods he thinks proper; ſo the profit left to the merchant is ſometimes little or nothing. All the money here is valued by the Venetian ſequin; and it is owing to the commercial intercourſe with the Arabian coaſt that any money at all is to be met with on this iſland or the eaſtern coaſt of Africa. Glaſs beads of all kinds and colours, whether whole or broken, paſs for ſmall money.

Though Maſſuah has now loſt very much of its commercial importance, a conſiderable trade is ſtill carried on from the place. From the Arabian ſide are imported blue cotton and other cloths; ſome of them from India being very fine. Other articles are Venetian beads, cryſtal, looking and drinking glaſſes, with cobol or crude antimony. Theſe three laſt articles come in great quantity from Cairo, firſt in the coffee-ſhips to Jidda, and then in ſmall barks to the port of Maſſuah. Old copper is alſo a valuable article of commerce. The Galla and all the various tribes to the weſtward of Gondar wear bracelets of this metal, which in ſome parts of that barbarous country is ſaid to ſell for its weight of gold. Here is alſo a ſhell, an univalve of the ſpecies of volutes, which ſells at an high price, and paſſes for money among the various

tribes of Galla. The Baſians were once the principal merchants of Maſſuah; but their number is now reduced to fix, who are ſilver-Smiths, and ſubſiſts by making ornaments for the women on the continent. They likewiſe eſſay gold, but make a poor livelihood.

MASSUET (Rene, or Renatus), a very learned Benedictine of the congregation of St Maur, was born at S. Owen de Macelles, in 1664. He is chiefly known for the new edition of St Irenæus, which he publiſhed in 1710. He conſulted ſeveral manuſcripts, which had never been examined, for that purpoſe, and made new notes and learned prefaces. He died in 1716, after having written and publiſhed ſeveral other works.

MAST, a long round piece of timber, elevated perpendicularly upon the keel of a ſhip, to which are attached the yards, the ſails, and the rigging. A maſt, with regard to its length, is either formed of one ſingle piece, which is called a *pole-maſt*, or composed of ſeveral pieces joined together, each of which retains the name of maſt ſeparately. The loweſt of theſe is accordingly named the *lower-maſt*, *a*, fig. 1. the next in height is the top-maſt, *b*, which is erected at the head of the former; and the higheſt is the top-gallant maſt, *c*, which is prolonged from the upper end of the top-maſt. Thus the two laſt are no other than a continuation of the firſt upwards.

The lower-maſt is fixed in the ſhip by an apparatus, deſcribed in the articles HULK and SHEERS: the foot, or heel of it, reſts in a block of timber called the *ſtep*, which is fixed upon the *keelson*: and the top-maſt is attached to the head of it by the *cap* and the *treſſle-trees*. The latter of theſe are two ſtrong bars of timber, ſupported by two prominences, which are as ſhoulders on the oppoſite ſides of the maſt, a little under its upper end: athwart theſe bars are fixed the *cross-trees*, upon which the frame of the top is ſupported. Between the lower-maſt-head and the foremoſt of the *cross-trees*, a ſquare ſpace remains vacant, the ſides of which are bounded by the two *treſſle-trees*. Perpendicularly above this is the foremoſt hole in the cap, whole after-hole is ſolidly fixed on the head of the lower-maſt. The top-maſt is erected by a tackle, whole effort is communicated from the head of the lower-maſt to the foot of the top-maſt; and the upper end of the latter is accordingly guided into and conveyed up through the holes between the *treſſle-trees* and the cap, as above-mentioned. The machinery by which it is elevated, or, according to the ſea-phraſe, *ſwayed up*, is fixed in the following manner: the top rope *d*, fig. 2. paſſing through a block *e*, which is hooked on one ſide of the cap, and afterwards through a hole, furniſhed with a ſheave or pulley *f*, on the lower end of the top-maſt, is again brought upwards on the other ſide of the maſt, where it is at length ſtrained to an eye bolt in the cap *g*, which is always on the ſide oppoſite to the top-block *e*. To the lower end of the top-rope is fixed the top-tackle *h*, the effort of which being tranſmitted to the top-rope *d*, and thence to the heel of the top-maſt *i*, neceſſarily liſts the latter upwards, parallel to the lower-maſt. When the top-maſt is raiſed to its proper height, fig. 3. the lower end of it becomes firmly wedged in the ſquare hole above deſcribed, between the *treſſle-trees*. A bar of wood or iron called the *ſid*, is then thruſt through a hole *i* in the heel of

Maſſuet,

Mast.

it, across the tressle-trees, by which the whole weight of the top-mast is supported.

In the same manner as the top-mast is retained at the head of the lower-mast, the top-gallant-mast is erected, and fixed at the head of the top-mast.

Besides the parts already mentioned in the construction of masts, with respect to their length, the lower-masts of the largest ships are composed of several pieces united into one body. As these are generally the most substantial parts of various trees, a mast, formed by this assemblage, is justly esteemed much stronger than one consisting of any single trunk, whose internal solidity may be very uncertain. The several pieces are formed and joined together, as represented in the section of a lower-mast of this sort, fig. 5, where *a* is the shaft, or principal piece into which the rest are fixed, with their sides or faces close to each other. The whole is secured by several strong hoops of iron, driven on the outside of the mast, where they remain at proper distances.

The principal articles to be considered in equipping a ship with masts are, 1st, the number; 2d, their situation in the vessel; and, 3d, their height above the water.

The masts being used to extend the sails by means of their yards, it is evident, that if their number were multiplied beyond what is necessary, the yards must be extremely short, that they may not entangle each other in working the ship, and by consequence their sails will be very narrow, and receive a small portion of wind. If, on the contrary, there is not a sufficient number of masts in the vessel, the yards will be too large and heavy, so as not to be managed without difficulty. There is a mean between these extremes, which experience and the general practice of the sea have determined; by which it appears, that in large ships every advantage of sailing is retained by three masts and a bowsprit.

The most advantageous position of the masts is undoubtedly that from whence there results an equilibrium between the resistance of the water on the body of the ship on one part, and of the direction of their effort on the other. By every other position this equilibrium is destroyed, and the greatest effort of the masts will operate to turn the ship horizontally about its direction; a circumstance which retards her velocity. It is counterbalanced indeed by the helm; but the same inconvenience still continues; for the force of the wind, having the resistance of the helm to overcome, is not entirely employed to push the vessel forward. The axis of the resistance of the water should then be previously determined, to discover the place of the *main-mast*, in order to suspend the efforts of the water equally, and place the other masts so as that their particular direction will coincide with that of the *main-mast*. The whole of this would be capable of a solution if the figure of the vessel were regular, because the point, about which the resistance of the water would be in equilibrium, might be discovered by calculation.

But when the real figure of the ship is considered, these flattering ideas will instantly vanish. This observation induced M. Savieren to employ a mechanical method to discover the axis of resistance of the water, which he apprehended might be used with success in the manner following:

When the vessel is launched, before the places of the masts are determined, extend a rope AB, fig. 6. from the head to the stern. To the extremities A and B attach two other ropes, AD, BC, and apply to the other ends of these ropes two mechanical powers, to draw the ship according to the direction BC, parallel to itself. The whole being thus disposed, let a moveable tube Z, fixed upon the rope AB, have another rope ZR attached to it, whose other end communicates with a mechanical power R, equal to the two powers D and C. This last being applied to the same vessel, in such manner as to take off the effects of the two others by sliding upon the rope AB, so as to discover some point Z, by the parallelism of the ropes AD, BC feebly extended with the rope ZR; the line ZR will be the axis of the equilibrium of the water's resistance, and by consequence the *main-mast* should be planted in the point Z.

The figures F, E, E, are three windlasses on the shore, by which this experiment is applied.

With regard to the situation of the other masts, it is necessary, in the same manner, to discover two points; so that the direction of the two mechanical powers operating, will be parallel to the axis of resistance RZ already found.

The exact height of the masts, in proportion to the form and size of the ship, remains yet a problem to be determined. The more the masts are elevated above the centre of gravity, the greater will be the surface of sail which they are enabled to present to the wind; so far an additional height seems to have been advantageous. But this advantage is diminished by the circular movement of the mast, which operates to make the vessel stoop to its effort; and this inclination is increased in proportion to the additional height of the mast, an inconvenience which it is necessary to guard against. Thus what is gained upon one hand is lost upon the other. To reconcile these differences, it is certain, that the height of the mast ought to be determined by the inclination of the vessel, and that the point of her greatest inclination should be the term of this height above the centre of gravity. See the article TRIM.

With regard to the general practice of determining the height of the masts, according to the different rates of the ships in the royal navy, the reader is referred to the article SAIL.

In order to secure the masts, and counterbalance the strain they receive from the effort of the sails impressed by the wind, and the agitation of the ship at sea, they are sustained by several strong ropes, extended from their upper ends to the outside of the vessel, called *shrouds*, as represented in fig. 4. They are further supported by other ropes, stretched from their heads towards the fore-part of the vessel.

The mast, which is placed at the middle of the ship's length, is called the *main-mast*; that which is placed in the forepart, the *fore-mast*; and that which is towards the stern, is termed the *mizen-mast*.

N. B. *Mizen* is applied to this mast by all the nations of Europe, except the French, who alone call the fore-mast *misaine*.

MASTER, a title given to several officers and persons of authority and command; particularly to the:

Mast.

Master.

Plate

CCLXXXI

Plate

CCLXXXI

Master.

the chiefs of the orders of knighthood, &c.—Thus we say the grand-master of Malta; of St Lazarus; of the golden fleece; of the free masons, &c.

MASTER (magister), was a title frequent among the Romans: they had their master of the people, *magister populi*, who was the dictator. Master of the cavalry, *magister equitum*, who held the second post in an army after the dictator. Under the later emperors there were also masters of the infantry, *magistri peditum*. A master of the census, *magister census*, who had nothing of the charge of a censor, or subcensor, as the name seems to intimate; but was the same with the *prepositus frumentariorum*.

MASTER of the Militia (magister militie), was an officer in the lower empire, created, as it is said, by Dioclesian, who had the inspection and government of all the forces, with power to punish, &c. somewhat like a constable of France. At first there were two of these officers instituted, the one for the infantry, and the other for the cavalry; but the two were united into one under Constantine. Afterwards, as their power was increased, so was their number also; and there was one appointed for the court, another for Thrace, another for the East, and another for Illyria. They were afterwards called *comites*, *counts*, and *clarissimi*. Their power was only a branch of that of the *praefectus praetorii*, who by that means became a civil officer.

MASTER of Arms (magister armorum), was an officer or comptroller under the master of the militia.

MASTER of the Offices (magister officiorum), had the superintendence of all the officers of the court: he was also called *magister officii palatini*; simply *magister*; and his post *magisterialis*.—This officer was the same in the western empire with the *curiales* in the eastern.

MASTER at Arms, among us, is an officer appointed to teach the officers and crew of a ship of war the exercise of small arms; to confine and plant sentinels over the prisoners, and superintend whatever relates to them during their confinement. He is also to observe that the fire and lights are all extinguished as soon as the evening-gun is fired, except those which are permitted by proper authority, or under the inspection of sentinels. It is likewise his duty to attend the gangway when any boats arrive aboard, and search them carefully, together with their rowers, that no spirituous liquors may be conveyed into the ship unless by permission of the commanding officer. In these several duties he is assisted by proper attendants, called his *corporals*, who also relieve the sentinels and one another at certain periods.

MASTER of Arts, the first degree taken up in foreign universities, but the second in ours; candidates not being admitted to it till they have studied in the university seven years.

MASTER-Attendant, is an officer in the royal dockyards, appointed to hasten and assist at the fitting out or dismantling, removing, or securing vessels of war, &c. at the port where he resides. He is particularly to observe, that his majesty's ships are securely moored, and for this purpose he is expected frequently to review the moorings which are sunk in the harbour, and observe that they are kept in proper repair. It is also his duty to visit all the ships in ordinary, and see that they are frequently cleaned and kept in or-

No 196.

der; and to attend at the general musters in the dockyards, taking care that all the officers, artificers, and labourers, registered at the navy-books, are present at their duty.

MASTER of the Ceremonies, is an officer instituted by King James I. for the more solemn and honourable reception of ambassadors, and strangers of quality, whom he introduces into the presence.—The badge of this office is a gold chain and medal, having on one side an emblem of peace, with King James's motto; and on the reverse the emblem of war, with *Dieu et mon droit*. He is always supposed to be a person of good address, and a master of languages, and has an appointment of 300l. a year: he is constantly attending at court, and hath under him an assistant-master, or deputy, at 6s. 8d. a day, who holds his place during the king's pleasure.

There is also a third officer, called *marshal of the ceremonies*, with 100l. a-year, whose business is to receive and distribute the master's order, or the deputy's, for the service; but without their order he can do nothing. This is the king's gift.

MASTERS of Chancery are usually chosen out of the barristers of the common law; and sit in chancery, or at the rolls, as assistants to the lord chancellor and the master of the rolls. All these, so late as the reign of Queen Elizabeth, were commonly doctors of the civil law.—To them are also committed interlocutory reports, examination of bills in chancery, stating of accounts, taxing costs, &c. and sometimes, by way of reference, they are empowered to make a final determination of causes.

They have time out of mind had the honour to sit in the lords house, though they have neither writ nor patent to empower them; but they are received as assistants to the lord chancellor and master of the rolls. They had anciently the care of inspecting all writs of summons, which is now performed by the clerk of the petty-bag. When any message is sent from the lords to the commons, it is carried by the masters of chancery. Before them also affidavits are made, and deeds and recognizances acknowledged.

Besides these, who may be called *masters of chancery ordinary* (being 12 in number, whereof the master of the rolls is reputed the chief), there are also masters of chancery extraordinary, appointed to act in the several counties of England beyond 10 miles distance from London, by taking affidavits, recognizances, &c. for the ease of the suitors of the court.

MASTER of the Faculties, an officer under the archbishop of Canterbury, who grants licences and dispensations: he is mentioned in the statute 22 and 23 Car. II. See *Court of Faculties*.

•*MASTER-Gunner*. See *GUNNER*.

MASTER of the Horse is reckoned the third great officer of the court, and is an office of great honour and antiquity, and always (when not put in commission) filled by noblemen of the highest rank and abilities. He has the management and disposal of all the king's stables and bred horses. He has authority over the equerries and pages, coachmen, footmen, grooms, riders of the great horse, farriers, and smiths. He appoints all the other tradesmen who work for the king's stables; and by his warrant to the avenor, makes them give an oath to be true and faithful. In short, he is

en-

Master.

entrusted with all the lands and revenues appropriated for the king's breed of horses, the expences of the stable, and of the coaches, litters, &c. He alone has the privilege of making use of any of the king's horses, pages, footmen, &c.; and at any solemn cavalcade he rides next the king, and leads a horse of state. His salary is £.1276 : 13 : 4 *per annum*. There is also a master of the horse in the establishment of her majesty's household, with a salary of 800*l.* a-year.

MASTER of the Household, is an officer under the treasurer of the household, in the king's gift : his business is to survey the accounts of the household.—He has £. 66 : 13 : 4 a-year wages, and £. 433 : 6 : 8 board-wages.

MASTER of the Mint, was anciently the title of him who is now called *warden of the mint* ; whose office is to receive the silver and bullion which comes to the mint to be coined, and to take care thereof. The office of master and worker is now distinct : and this officer is allowed for himself and three clerks 650*l.* a-year.

MASTER of the Ordnance. See *ORDNANCE*.

MASTER of the Revels, an officer with an appointment of 100*l.* a-year, whose business is to order all things relating to the performance of plays, masques, balls, &c. at court. Formerly he had also a jurisdiction of granting licences to all who travel to act plays, puppet-shows, or the like diversions ; neither could any new play be acted at either of the two houses till it had passed his perusal and licence ; but these powers were afterwards much abridged, not to say annihilated, by a statute for regulating playhouses, till the licensing plays by the lord chamberlain was established. This officer has a yeoman with £.46 : 11 : 8 a-year.

MASTER of the Rolls, a patent-officer for life ; who has the custody of the rolls and patents which pass the great seal, and of the records of the chancery.

In the absence of the lord chancellor or keeper, he also sits as judge in the court of chancery ; and is by Sir Edward Coke called his *assitant*.

At other times he hears causes in the rolls-chapel, and makes orders and decrees. He is also the first of the masters of chancery, and has their assistance at the rolls : but all hearings before him are appealable to the lord chancellor.

He has also his writ of summons to parliament, and sits next to the lord chief justice of England on the second woolpack. He has the keeping of the parliament-rolls, and has the rolls-house for his habitation ; as also the custody of all charters, patents, commissions, deeds, and recognizances, which being made of rolls of parchment gave rise to the name. Anciently he was called *clerk of the rolls*.

Concerning the authority of the master of the rolls to hear and determine causes, and his general power in the court of chancery, there were (not many years since) divers questions and disputes very warmly agitated ; to quiet which it was declared by stat. 3. Geo. II. cap. 30. that all orders and decrees by him made, except such as by the course of the court were appropriated to the great seal alone, should be deemed to be valid ; subject nevertheless to be discharged or altered by the lord chancellor, and so as they shall

not be inrolled till the same are signed by his lordship.

In his gift are the six clerks in chancery, the examiners, three clerks of the petty-bag, and the six clerks of the rolls-chapel where the rolls are kept. See *ROLLS*, *CLERK*, &c.

The master of the rolls is always of the privy-council ; and his office is of great profit, though much short of what it has been.

MASTER of a Ship, an officer to whom is committed the direction of a merchant-vessel, who commands it in chief, and is charged with the merchandises aboard.

In the Mediterranean the master is frequently called *patron*, and in long voyages *captain*.

It is the proprietor of the vessel that appoints the master ; and it is the master who provides the equipment, hires the pilots, sailors, &c. The master is obliged to keep a register of the seamen and officers, the terms of their contract, the receipts and payments, and, in general, of every thing relating to his commission.

MASTER of a Ship of War, is an officer appointed by the commissioners of the navy, to take charge of navigating a ship from port to port under the direction of the captain. The management and disposition of the sails, the working of a ship into her station in the order of battle, and the direction of her movements in the time of action, and in other circumstances of danger, are also more particularly under his inspection. It is likewise his duty to examine the provisions, and accordingly to admit none into the ship but such as are sound, sweet, and wholesome. He is moreover charged with the stowage ; and for the performance of these services he is allowed several assistants who are properly termed *mates* and *quarter-masters*.

MASTER of the Temple. The founder of the order of the templars, and all his successors were called *magni templi magistri* ; and ever since the dissolution of the order, the spiritual guide and director of the house is called by that name. See *TEMPLE* and *TEMPLAR*.

There were also several other officers under this denomination, as master of the wardrobe, with a salary of 2000*l.* a-year ; master of the harriers, with 2000*l.* a-year ; master of the stag-hounds, with 800*l.* a-year ; master of the jewel-office, &c. all now abolished.

MASTER and Servant ; a relation founded in convenience, whereby a man is directed to call in the assistance of others, where his own skill and labour will not be sufficient to answer the cares incumbent upon him. For the several sorts of servants, and how that character is created or destroyed, see the article *SERVANT*. In the present article we shall consider, first, the effect of this relation with regard to the parties themselves ; and secondly, its effects with regard to others.

1. The manner in which this relation affects either the master or servant. And, first, by hiring and service for a year, or apprenticeship under indentures, a person gains a settlement in that parish wherein he last served 40 days. In the next place, persons serving seven years as apprentices to any trade have an exclusive right to exercise that trade in any part of England. This law, with regard to the exclusive part of

*Blacks.
Comment.*

Master.

it, has by turns been looked upon as a hard law, or as a beneficial one, according to the prevailing humour of the times: which has occasioned a great variety of resolutions in the courts of law concerning it; and attempts have been frequently made for its repeal, tho' hitherto without success. At common law every man might use what trade he pleased; but this statute restrains that liberty to such as have served as apprentices: the adversaries to which provision say, that all restrictions (which tend to introduce monopolies) are pernicious to trade; the advocates for it allege, that unskilfulness in trades is equally detrimental to the public as monopolies. This reason indeed only extends to such trades, in the exercise whereof skill is required: but another of their arguments goes much farther; viz. that apprenticeships are useful to the commonwealth, by employing of youth, and learning them to be early industrious; but that no one would be induced to undergo a seven years servitude, if others, tho' equally skilful, were allowed the same advantages without having undergone the same discipline: and in this there seems to be much reason. However, the resolutions of the courts have in general rather confined than extended the restriction. No trades are held to be within the statute, but such as were in being at the making of it: for trading in a country village, apprenticeships are not requisite, and following the trade seven years is sufficient without any binding; for the statute only says, the person must serve *as an apprentice*, and does not require an actual apprenticeship to have existed.

A master may by law correct his apprentice for negligence or other misbehaviour, so it be done with moderation: though, if the master or master's wife beats any other servant of full age, it is good cause of departure. But if any servant, workman, or labourer, assaults his master or dame, he shall suffer one year's imprisonment, and other open corporal punishment, not extending to life or limb.

By service all servants and labourers, except apprentices, become intitled to their wages: according to agreement, if menial servants; or according to the appointment of the sheriff or sessions, if labourers or servants in husbandry: for the statutes for regulation of wages extend to such servants only; it being impossible for any magistrate to be a judge of the employment of menial servants, or of course to assess their wages.

2. Let us now see how strangers may be affected by this relation of master and servant; or how a master may behave towards others on behalf of his servant, and what a servant may do on behalf of his master.

And, first, the master may *maintain*, that is, abet and assist, his servant in any action at law against a stranger: whereas, in general, it is an offence against public justice to encourage suits and animosities, by helping to bear the expence of them, and is called in law *maintenance*. A master also may bring an action against any man for beating or maiming his servant: but in such case he must assign, as a special reason for so doing, his own damage by the loss of his service; and this loss must be proved upon the trial. A master likewise may justify an assault in defence of his servant,

Master.

and a servant in defence of his master: the master, because he has an interest in his servant, not to be deprived of his service; the servant, because it is part of his duty, for which he receives his wages, to stand by and defend his master. Also if any person do hire or retain my servant, being in my service, for which the servant departeth from me and goeth to serve the other, I may have an action for damages against both the new master and the servant, or either of them: but if the new master did not know that he is my servant, no action lies; unless he afterwards refuse to restore him upon information and demand. The reason and foundation upon which all this doctrine is built, seem to be the property that every man has in the service of his domestics; acquired by the contract of hiring, and purchased by giving them wages.

As for those things which a servant may do on behalf of his master, they seem all to proceed upon this principle, that the master is answerable for the act of his servant, if done by his command, either expressly given or implied: *nam qui facit per alium, facit per se*. Therefore, if the servant commit a trespass by the command or encouragement of his master, the master shall be guilty of it: not that the servant is excused, for he is only to obey his master in matters that are honest and lawful. If an innkeeper's servants rob his guests, the master is bound to restitution; for as there is a confidence reposed in him, that he will take care to provide honest servants, his negligence is a kind of implied consent to the robbery; *nam, qui non prohibet, cum prohibere possit, jubet*. So likewise if the drawer at a tavern sells a man bad wine, whereby his health is injured, he may bring an action against the master; for although the master did not expressly order the servant to sell it to that person in particular, yet his permitting him to draw and sell it at all is impliedly a general command.

In the same manner, whatever a servant is permitted to do in the usual course of his business, is equivalent to a general command. If I pay money to a banker's servant, the banker is answerable for it: if I pay it to a clergyman's or a physician's servant, whose usual business it is not to receive money for his master, and he imbezcles it, I must pay it over again. If a steward lets a lease of a farm, without the owner's knowledge, the owner must stand to the bargain; for this is the steward's business. A wife, a friend, a relation, that use to transact business for a man, are *quoad hoc* his servants; and the principal must answer for their conduct: for the law implies, that they act under a general command; and without such a doctrine as this no mutual intercourse between man and man could subsist with any tolerable convenience. If I usually deal with a tradesman by myself, or constantly pay him ready money, I am not answerable for what my servant takes up upon trust; for here is no implied order to the tradesman to trust my servant: but if I usually send him upon trust, or sometimes on trust and sometimes with ready money, I am answerable for all he takes up; for the tradesman cannot possibly distinguish when he comes by my order and when upon his own authority.

If a servant, lastly, by his negligence does any damage to a stranger, the master shall answer for his neglect:

Maſter
||
Maſtic.

glect: if a ſmith's ſervant lames a horſe while he is ſhoeing him, an action lies againſt the maſter, and not againſt the ſervant. But in theſe caſes the damage muſt be done while he is actually employed in the maſter's ſervice; otherwiſe the ſervant ſhall anſwer for his own miſbehaviour. Upon this principle, by the common law, if a ſervant kept his maſter's fire negligently, ſo that his neighbour's houſe was burned down thereby, an action lay againſt the maſter; becauſe this negligence happened in his ſervice: otherwiſe, if the ſervant, going along the ſtreet with a torch, by negligence ſets fire to a houſe; for there he is not in his maſter's immediate ſervice, and muſt himſelf anſwer the damage perſonally. But now the common law is, in the former caſe, altered by ſtatute 6 Ann. c. 3. which ordains, that no action ſhall be maintained againſt any in whole houſe or chamber any fire ſhall accidentally begin; for their own loſs is ſufficient puniſhment for their own or their ſervant's careleſſneſs. But if ſuch fire happens through negligence of any ſervant (whoſe loſs is commonly very little), ſuch ſervant ſhall forfeit (col. to be diſtributed among the ſufferers; and, in default of payment, ſhall be committed to ſome workhouſe, and there kept to hard labour for 18 months. A maſter is, laſtly, chargeable if any of his family layeth or caſteth any thing out of his houſe into the ſtreet or common highway, to the damage of any individual, or the common nuisance of his majeſty's liege people: for the maſter hath the ſuperintendence of all his houſehold. And this alſo agrees with the civil law; which holds, that the *pater familias*, in this and ſimilar caſes, *ob alterius culpam tenetur, ſive ſervi, ſive liberi*.

We may obſerve, that in all the caſes here put, the maſter may be frequently a loſer by the truſt reposed in his ſervant, but never can be a gainer: he may frequently be answerable for his ſervant's miſbehaviour, but never can ſhelter himſelf from puniſhment by laying the blame on his agent. The reaſon of this is ſtill uniform and the ſame; that the wrong done by the ſervant is looked upon in law as the wrong of the maſter himſelf; and it is a ſtanding maxim, that no man ſhall be allowed to make any advantage of his own wrong.

MASTER-Load, in mining, a term uſed to expreſs the larger vein of a metal, in places where there are ſeveral veins in the ſame hill. Thus it often happens, that there are ſeven, ſometimes five, but more uſually three veins or loads, parallel to each other, in the ſame hill. Of theſe the middle vein is always much the largeſt. This is called the *maſter-load*; and the others which lie three, two, or one on each ſide of this, are called the *concomitants* of the maſter-load.

MASTER-Word, in botany. See **IMPERATORIA**.

MASTICATION, the action of chewing, or of agitating the ſolid parts of our food between the teeth, by the motion of the jaws, the tongue, and the lips, whereby it is broken into ſmall pieces, impregnated with ſaliva, and ſo fitted for degluſtion and a more eaſy digeſtion. See **ANATOMY**, n° 104.

MASTICH, a kind of reſin exuding from the lenticeſcus tree; and brought from Chio, in ſmall yellowiſh tranſparent grains or tears, of an agreeable ſmell, eſpecially when heated or ſet on fire. See **PISTACHIA**.

This reſin is recommended in old coughs, dyſenteries, hæmopto's, weakneſs of the ſtomach, and in general in all debilities and laxity of the fibres. Geoffroy directs an aqueous decoction of it to be uſed for theſe purpoſes: but water extracts little or nothing from this reſin. Rectified ſpirit almoſt entirely diſſolves it, and the ſolution is very warm and pungent. Maſtic is to be choſen in drops, clear, well-ſcented, and brittle.

We meet with a kind of cement ſometimes kept in the ſhops under the name of maſtic. It is compoſed of this gum, and ſeveral other ingredients, and is formed into cakes for uſe. This is intended for the ſervice of lapidaries, to fill up cracks in ſtones, &c. but is by no means to be uſed for any medicinal purpoſes.

MASTICOT, or **YELLOW LEAD**, is the calx or aſhes of lead, gently calcined, by which it is changed to a yellow or lighter or deeper teint, according to the degree of calcination. Maſticot is ſometimes uſed by painters, and it ſerves medicinally as a drier in the compoſition of ointments or plaiſters. The maſticot which is uſed by the Dutch as the ground of their glazing, is prepared by calcining a mixture of one hundred weight of clean ſand, forty-four pounds of ſoda, ſold wiſh us under the name of barilla, and thirty pounds of pearl-aſhes.

MASTIFF-DOG, or **BAND-DOG**, (*canis villaticus* or *catenarius*), is a ſpecies of great ſize and ſtrength, and a very loud barker. Manwood ſays, that it derives its name from *maſte theſſe*, being ſuppoſed to frighten away robbers by its tremendous voice. Great Britain was formerly ſo noted for its maſtiſſs, that the Roman emperors appointed an officer in this iſland, with the title of *Procurator Cynegii*, whoſe ſole buſineſs was to breed, and tranſmit from hence to the amphitheatre, ſuch as would prove equal to the combats of the place. Strabo, lib. iv. tells us, that the maſtiſſs of Britain were trained for war, and uſed by the Gauls in their battles. See **CANIS**.

MASTIGADOUR, or **SLABBERING-BIT**, in the manege, a ſnaffle of iron, all ſmooth, and of a piece, guarded with paternoſters, and compoſed of three halves of great rings, made into demi-ovals, of unequal bigneſs; the leſſer being incloſed within the greater, which ought to be about half a foot high.

MASULAPATAN, a populous town of Aſia in the Eaſt Indies, and on the coaſt of Coromandel, in the dominions of the Great Mogul. It carried on a great trade, and moſt nations in Europe had factories here; but the Engliſh have now left it, and even the Dutch themſelves have not above a dozen people here to carry on the chintz trade. The inhabitants are Gentoos, who will not feed on any thing that haſt life; and they had a famous manufacture of chintz, which is greatly decayed ſince the Engliſh left off buying. The Great Mogul has a cuſtom-houſe here; and the adjacent countries abound in corn, tobacco, and timber for building. It is ſeated on the welt ſide of the Bay of Bengal, 200 miles north of fort St George. W. Long. 81. 25. N. Lat. 16. 30.

MATACA, or **MANTACA**, a commodious bay in America, on the north coaſt of the iſland of Cuba. Here the galleons uſually come to take in freſh water

Maſticot
||
Mataca.

Mataman in their return to Spain. It is 35 miles from the Havannah. W. Long. 85. 6. N. Lat. 25. 0.

Matching.

MATAMAN, a country of Africa, bounded by Benguela on the north, by Monomotopa on the east, by Cafria on the south, and by the Atlantic Ocean on the west. There is no town in it, and the inhabitants live in miserable huts, it being a desert country, and but little visited by the Europeans.

MATAN, or **MATAN**, an island of Asia in the East-Indian sea, and one of the Philippines. The inhabitants have thrown off the yoke of Spain; and it was here that Magellan was killed in April 1521.

Cape MATAPAN, the most southern promontory of the Morea, between the gulph of Corau and that of Colo-China.

MATARAM, a large town of Asia, formerly the capital of an empire of that name in the island of Java. It is strong by situation, and is seated in a very fertile, pleasant, and populous country, surrounded with mountains. E. Long. 111. 25. S. Lat. 7. 55.

MATARO, a town of Spain, in Catalonia; seated on the coast of the Mediterranean, 15 miles north-east of Barcelona, and 35 south-west of Gironne. It is a small town, but industrious and well-peopled; and the environs abound in vineyards, which produce wine much famed for its flavour. It likewise contains several manufactories, and is considered as one of the richest and most active towns in Catalonia. E. Long. 2. 35. N. Lat. 41. 30.

MATCH, a kind of rope slightly twisted, and prepared to retain fire for the uses of artillery, mines, fire-works, &c.

It is made of hempen-tow, spun on the wheel like cord, but very slack; and is composed of three twits, which are afterwards again covered with tow, so that the twits do not appear: lastly, it is boiled in the lees of old wines. This, when once lighted at the end, burns on gradually and regularly, without ever going out till the whole be consumed: the hardest and driest match is generally the best.

Quick-Match. See *Quick-Match*.

MATCHING, in the wine-trade, the preparing vessels to preserve wines and other liquors, without their growing foul or vapid. The method of doing it is as follows: Melt brimstone in an iron ladle, and when thoroughly melted, dip into it slips of coarse linen-cloth; take these out, and let them cool: this the wine-coopers call a *match*. Take one of these matches, set one end of it on fire, and put it into the bung-

hole of a cask; stop it loosely, and thus suffer the match to burn nearly out: then drive in the bung tight, and set the cask aside for an hour or two. At the end of this time examine the cask, and you will find that the sulphur has communicated a violent pungent and suffocating scent to the cask, with a considerable degree of acidity, which is the gas and acid spirit of the sulphur. The cask may after this be filled with a small wine which has scarce done its fermentation; and bunging it down tight, it will be kept good, and will soon clarify: this is a common and very useful method; for many poor wines could scarce be kept potable even a few months without it.

MATE of a *SHIP OF WAR*, an officer under the direction of the master, by whose choice he is generally appointed, to assist him in the several branches of his duty. Accordingly, he is to be particularly attentive to the navigation in his watch, &c. to keep the *log* regularly, and examine the line and glasses by which the ship's course is measured, and to adjust the sails to the wind in the fore-part of the ship. He is to have a diligent attention to the cables, seeing that they are well coiled and kept clean when laid in the tier, and sufficiently served when employed to ride the ship. Finally, he is to superintend and assist at the stowage of the hold, taking especial care that all the ballast and provisions are properly stowed therein.

MATE of a *Merchant-Ship*, the officer who commands in the absence of the master thereof, and shares the duty with him at sea; being charged with every thing that regards the internal management of the ship, the directing her course, and the government of her crew.

The number of mates allowed to ships of war and merchantmen is always in proportion to the size of the vessel. Thus a first-rate man of war has six mates, and an East-Indiaman the same number; a frigate of 10 guns, and a small merchant-ship, but only one mate in each; and the intermediate ships have a greater or smaller number, according to their several sizes, or to the services on which they are employed.

DURA and **PIA MATER**, the names given by anatomists to the two membranes which surround the brain. See *ANATOMY*, n° 129, 130.

MATERA, a considerable town of Italy, in the kingdom of Naples, and in the Terra d'Otranto, with a bishop's see, seated on the river Canaparo. E. Long. 16. 43. N. Lat. 40. 51.

M A T E R I A M E D I C A,

Of Classification.

A GENERAL name for every substance used in medicine, and by some extended even to every article used as food or drink.

Thus the materia medica becomes exceedingly extensive; however, before we enter upon any particular discussion of the subject, it appears proper to give some general idea of medicines and their operation.

A *medicine*, properly so called, is a substance which, when applied to the living human body, makes such an alteration in it as either to prevent the approach of disease, or to remedy a morbid state when already present.

Such substances as may be used for these purposes without any great preparation are called *simple medicines*, or *simples*; and with these the writers on materia medica are chiefly conversant. In treatises written professedly on this subject, it is common to give a particular description of each article, the characteristic marks by which it may be distinguished from all other substances, and the methods by which an adulteration or an imperfection may be discovered in it, together with the dose in which it can safely be given: but as all these particulars are taken notice of in different

Mate, Matera.

Of Classification.

different parts of this work, it is only necessary here to mention the general classification, and enumerate the names of the various substances used in medicine, after giving, as hath been already promised, a brief and general account of their mode of operation.

Concerning the manner in which medicines act, physicians have greatly differed, and each has followed his own particular theory. The followers of Boerhaave have supposed their action to be directly upon the solids and fluids; while those who build their theories on the hypothesis of Hoffman have asserted, that all medicines act immediately upon the nervous system, and from thence only in a secondary manner are their effects diffused over the solids and fluids. To discuss this question is not our business at present: neither indeed is it a matter of great consequence whether it be discussed or not; seeing all parties must own, that certain effects follow the use of certain particular substances, whether these substances act first upon the nervous system or upon the solids and fluids.

From their operations on the human body medicines are most usually divided into classes. Some are found to have the property of rendering the solid parts of the body more lax than before, and are therefore called *relaxing* medicines: Others there are which have an effect directly contrary, and are therefore called *indurating* medicines: A third kind are found to excite inflammation in the part to which they are applied, and are therefore called *inflammatory* medicines: And, lastly, a fourth kind are found remarkably either to increase or diminish the vigour of the body, or what is called the *tone* of the solids; and have therefore got the name of *tonics* if they increase, and *sedatives* if they diminish, this tone.

Some medicines are supposed neither remarkably to increase nor diminish the tone of the solids; but to perform their office either by correcting some morbid matter in the body, or by evacuating it: in the former case they are called *alterants*, in the latter *evacuants*.

These are the general divisions or classes into which medicines are commonly divided; but when we begin more particularly to consider their virtues, a great many inferior divisions arise.—Of the relaxing medicines, some, when externally applied, are supposed only to soften the part; and in that case are called *emollients*: while others, which have a power of converting the humours stagnating in any inflamed part into pus, are called *maturants*, or *suppuratives*. Sedative medicines, externally applied, are sometimes called *paregories*: when taken internally, if they take off a spasm then existing in the body, they are called *antispasmodics*; if they mitigate pain, *anodynes*; if they produce a quiet sleep, *hypnotics*; or if they produce a very deep and unnatural sleep, together with a remarkable stupefaction of the senses, they are then called *narcotics*.

Tonic medicines obtain the name of *corroboratives*, *analptics*, or *nervine* medicines, when they slightly increase the contractile power of the solids; but of *astringents*, if they do this in a great degree, especially if at the same time that they indurate the solids they also coagulate the fluids. Some of these medicines have received names from their supposed virtue of pro-

moting the growth of the flesh, consolidating wounds, and stopping fluxes of blood: but it is now discovered that no medicines whatever are endowed with any such powers; and therefore the divisions into *sarcotics* *traumaticis*, or *vulneraries*, &c. are seldom used.

—If astringent medicines are used with an intention to drive, by the constriction which they occasion, any kind of matter from the surface towards the internal parts of the body, they are called *repellents*; but if they insensibly expel any kind of stagnating matter from the parts where it is contained, they are then called *discutients*; and lastly, *stimulants*, or *atractives*, if they bring a greater flux of humours to the part to which they are applied.

As to medicines of the inflammatory kind, they are divided into *vesicatories* or blisters, which by their application raise watery bladders on the skin; and *cathartics*, *eghoratics*, or *corrosives*, if they eat into and destroy the substance of the solid parts themselves. Another subdivision has been added, viz. that of *rube-factive* medicines, or such as only induce a redness on the part to which they are applied; but these belong to the vesicatories, and what proves only *rube-factive* to one will frequently blister another.

The alterants are divided into *absorbents*, such as by their alkaline quality neutralise and destroy any acid matter which may be in the stomach; and *antiseptics*, or those which correct any putrid matter in it; *coagulants* when they thicken the humours, and *resolvents* if they thin them; *heating* medicines when they increase the velocity of the blood, and *refrigerating* if they diminish it.

The evacuating medicines are divided according to the nature of the humour they evacuate. Thus, if they evacuate the contents of the stomach by vomiting, they are called *emetics*; if they induce purging, they are called *cathartics*; if they only evacuate the immediate contents of the intestines, they are named *ecoproctics*; or if a moderate evacuation is produced, without sickness or pain, they are called *laxatives*.—The medicines which gently promote the expulsion of humours through the pores of the skin, are called *diaphoretics*. If they do this in great quantity and with violence, they are called *sudorifics*. Such as excite urine, are called *diuretics*. Such as produce their evacuation by the glands of the palate, mouth, and salivary ducts, are called *salivatory* medicines; those which promote the evacuation of mucus from the throat, are called *apoplegmatics*; while those which evacuate by the nose, are called *ptarmics*, *errhines*, *sternutatories*; and those which promote the menstrual flux, *emmenagogues*.—To the order of evacuants also some reduce those medicines which expel any unnatural bodies, as worms, stones, and flatus. Those which destroy worms are called *anthelmintics*; those which dissolve the stone in the bladder, *lithoniptics*; and such as expel flatus, *carminatives*.

According to these divisions Mr Vogel classes the articles of his *Materia Medica*; but Dr Lewis chooses to arrange them according to the natural qualities of the substances themselves, and not their effects on the human body.

Writers on the *materia medica* (he observes) have taken great pains in arranging the various articles of which

which it is composed, into different divisions and subdivisions, according to their real or reputed medicinal powers.

It has been imagined, that the whole materia medica is reducible under the three distinctions of *alteratives*, *evacuants*, and *reforvatives*: the first comprehending all that has any power to alter the constitution, without sensibly increasing or diminishing any of the natural evacuations; the second, whatever visibly promotes those discharges; and the third, all that contributes to lessen them, and make the increase greater than the waste. These divisions being too general, they are broken into subdivisions; and these again are further divided into different classes, under more restrained denominations, as cardiac, carminative, hysseric, stomachic, &c.

Specious as this plan may appear to be, he imagines the execution of it, to any useful purpose, would require a far more extensive knowledge of the nature and operation of medicines than has yet been attained to. A just and useful method of simples is scarcely to be expected, while those properties on which the method is founded are imperfectly known, and in many articles only conjectural.

In all the arguments that have been hitherto contrived upon this plan, there appears a striking incongruity among the several articles of which even the ultimate subdivisions are composed; substances extremely dissimilar being classed together, as cantharides and tea, tobacco and bran, hemlock and cowslips, scurvy-grass and raisins, arum root and liquorice, wormwood and parsnips, cinnamon and nettles, raspberries and chalk, artichokes and alum, cloves and coffee, mustard-seed and black cherries, &c. Nor are these incongruities to be laid always to the charge of the authors, the nature of the system itself rendering them often unavoidable; for the particular effect which intitles a medicine to a particular class, may be produced by substances very dissimilar, and even opposite, in their general powers: thus the alvine excretions are restrained by starch, wax, tormentil-root, opium; among the capital diuretics are cantharides, nitre, salt, fixt alkaline salts, squills. It should seem that the method of arrangement cannot be a just one which requires substances so discordant to be ranked together, and which further requires each of these substances to be ranked over again, in other classes, along with other substances to which they are equally discordant.

There is also a material imperfection in this scheme, even in the primary divisions. Steel and its preparations act, in different circumstances, both as evacuants and reforvatives. Mercury and antimony afford, in their different preparations, both evacuants and alteratives; and there are many other drugs which are sometimes used as alteratives, and sometimes as evacuants; indeed, all evacuants, in diminished doses, seem to act merely as alteratives. It should seem therefore, that "the division of the whole materia medica into alteratives, evacuants, and reforvatives," is a division not founded in nature, even if there was no objection to the vague meaning of the appellations themselves.

Cartheuser has divided the materia medica on a

plan which appears more rational. Instead of the operations of medicines in the human body, which are precarious, complicated, and greatly diversified according to the dose, the preparation, and the circumstances of the patient, he takes for the basis of his arrangement their more simple, obvious, and constant properties, as bitterness, sweetness, astringency, acidity, &c. Having considered the nature of bitterness, for instance, in general, he examines what effects medicines possessed of this property are capable of producing in the body, and in what circumstances they may be expected to be serviceable, and then proceeds to an account of the particular bitters.

This method is of real use, but its use is limited to a small part of the materia medica. There are many of the medicinal simples, in which we can distinguish no prevailing qualities of this kind; there are many, in which different qualities are blended together; and many which, though similar in these kinds of qualities, are very dissimilar in their operations in the human body: thus though gentian and aloe agree in having a bitter taste, and sugar and manna in being sweet, their medicinal virtues are respectively very different. Accordingly, the author is obliged in some cases to depart from his general plan, and found the division on the medicinal effects: he makes one class of purgatives and emetics, and another of vaporous inebriants and narcotics: this last class consists of tobacco, elder-flowers, saffron, opium, and poppy-seeds, substances certainly very discordant in all their qualities that relate to medicinal intentions.

In this article, instead of attempting a medicinal distribution of the simples, which we apprehend not to be practicable to any good purpose, we shall, after Dr Lewis, adopt the alphabetical mode of arrangement, as possessing upon the whole a decided superiority over every other. We shall, however, premise, from the same ingenious author, some general observations on certain classes of medicines, in Cartheuser's manner; and thus preserve the less exceptionable parts of his plan, with some amendments.

ART. I. ACIDS.

- | | | |
|---------------------------|---|--|
| | { | native; as sorrel, wood-sorrel, juice of lemon, oranges, barberries, and other fruits.
produced by fermentation; as vinegar and tartar. |
| | | |
| Class 1. <i>Vegetable</i> | | |
| Class 2. <i>Mineral</i> : | | the acids of vitriol, nitre, and common salt. |

THE medical effects of acids, duly diluted and given in proper doses, are, to cool, quench thirst, correct a tendency to putrefaction, and allay inordinate motions of the blood. By these qualities, in hot bilious temperaments and inflammatory disorders, they frequently restrain immoderate hæmorrhages, and promote the natural secretions; in some kinds of fever, they excite a copious diaphoresis, where the warm medicines, called *alexipharmics*, tend rather to prevent this salutary discharge.

Vegetable acids, particularly the native juices of certain plants and fruits, have some degree of a sapaceous quality; by means of which they attenuate

Absorbents, or dissolve viscid phlegm and deterge the vessels, and thus prove serviceable in sundry chronic disorders. Inveterate scurvy have sometimes yielded to their continued use, especially when given in conjunction with medicines of the acid or pungent kind: experience has shown, that the acid antiscorbutics have much better effects when thus managed than when exhibited by themselves; hence in the *Juci scorbutici* of our dispensatory, Seville orange juice is usefully joined to that of the *cochlearia* and *nasurtium*.

The mineral acids instantly coagulate blood: the vegetable dilute it, even when inspissated or thickened by heat; in which state, watery liquors will not mingle with it. Hence, in some fevers, where water runs off by the kidneys almost as pale and insipid as it was drank, vegetable acids render the urine of the due colour and quality. The mineral acids (the spirit of nitre in particular) combined with vinous spirits, have a like effect.

Acids are prejudicial in cold, pale, phlegmatic habits, where the vessels are lax, the circulation languid, bile deficient, and the power of digestion weak. In these cases, an acid is often generated in the stomach, from milk and moist vegetable foods; which, whilst it continues in the first passages, occasions uneasiness about the stomach, flatulencies, sometimes griping pains of the bowels, and vomitings.

ART II. INSIPID EARTHS *capable of* ABSORBING ACIDS.

Oyster-shells,	Chalk,
Crabs claws and eyes so called,	Some marles,
Coral, red and white,	Lime-stones,
Pearls,	Marbles,
Bezoar,	Spars.

The virtues of these substances are, to absorb or destroy acidities in the first passages, and consequently to remove such disorders as proceed from that cause. The cordial, alexipharmic, antifebrile, and other like virtues attributed to these medicines, appear to have little foundation; or at best are only secondary ones. When united with the acid, they form a neutral saline compound, possessing some degree of an aperient and detergent quality, though too inconsiderable to be in general regarded.

The absorbent earths were all strangers to medicine in the earlier times; and their use does not seem to have been established before the last century; when some practitioners, from an opinion that most kinds of diseases proceeded from a preternatural acid, introduced a great variety of antacid bones, both of the earthy and saline kind, and very liberally exhibited them on almost every occasion.

It is certain, that in children, and adults of a weak constitution, and whose food is chiefly of the vegetable acescent kind, sundry disorders are occasioned by acidities; these readily discover themselves by four eruptions, the pale colour of the face, and in children by the four smell and green colour of the alvine faeces, which are sometimes so manifestly acid as to raise a strong effervescence with alkaline salts. In

these cases, and these only, the use of absorbent earths **Absorbents** is indicated.

If there are really no acid juices in the ventricle, these earths are apt to concreate with the mucous matter usually lodged there, into hard indissoluble masses; which have sometimes been thrown up by vomit, or found in the stomach upon dissection. Hence indigestion, loss of appetite, nausea, vomiting, obstructions of the bowels, and other disorders. Sometimes the stomach and intestines have been found lined with a crust, as it were, of these earthy bodies, which must not only have prevented the separation of the gastric liquor, but likewise have closed the orifices of the lacteal vessels, so as to obstruct the passage of the chyle into the mass of blood.

Some suppose the earthy powders capable (without the concurrence of any acid) of passing the lacteals along with the chyle; and allege, in support of this opinion, that, when triturated with water, they are in part taken up and carried with it through a filter of paper; the filtrated liquor leaving, upon evaporation, a portion of whitish earthy matter. This experiment (allowing the consequence to be justly drawn from it) is itself erroneous: the residuum proceeds from the earth naturally contained in the water, not from that employed in the experiment; for if pure distilled water be made use of, it will leave no residuum, though long triturated or digested with the earth.

All these bodies, particularly those of the animal kind, contain, besides their purely alkaline earth, a portion of glutinous matter. An instance of this we have in crabs-eyes, which if macerated in the weaker acids, or in the stronger sufficiently diluted with water, the earthy part will be dissolved, and the animal-glue remain in form of a soft transparent mucilage. The glutinous substance increases their tendency to concreate in the stomach; and thence those which contain least thereof should be preferred to the others. The mineral earths contain the least of this kind of matter, and some of them are very easy of solution; chalk, for instance, which may therefore be given with greater safety than the animal-absorbents. These substances, divested of their conglutinating matter by means of fire, are reduced into acrimonious calces or limes, and thus become medicines of a different class.

The teeth, bones, hoof, and horns of animals consist of the same principles with the animal-absorbents above mentioned, but combined in different proportions: the quantity of gelatinous matter is so large, as to defend the earthy part from the action of weak acids; whilst the earth, in its turn, protects the gluten from being easily dissolved by watery liquors. Hence these bodies in their crude state, though recommended as possessing singular virtues, are not found to have any virtue at all.

Experiments have been made for determining the degree of solubility, or comparative strength of these earths; the principal of which are arranged in the two following tables, one taken from Langius, and the other from Homberg.

Absorbents.

TABLE of the quantity of Acid destroyed by different Absorbents.

Ten grains of	Some kinds of Limestone	destroyed the acidity of	160
	Oyster shells		120
	Chalk		100
	Shells of Garden-snails		100
	Calcined Cray-fish		100
	Pearls		80
	Tooth of the Sea-horse		80
	Volatile Salts		80
	Fixed Salts		60
	Coral, red and white		60
	Crabs-eyes		50
	Egg-shells		50
	Mother-of-Pearl		50
	Crabs-claws		40
	Jaw-bone of the Pike-fish		30

Drops of Spirit of Salt.

TABLE of the quantity of Absorbent Earths soluble in Acids.

576 grains of Spirit of Salt dissolved of	Crabs-eyes	216
	Mother-of-Pearl	144
	Pearls	128
	Oyster-shells	156
	Hartshorn	165
	Coral	186
	Oriental Bezoar	118
	Occidental Bezoar	123
576 grains of Spirit of Nitre dissolved of	Quick Lime	199
	Slacked Lime	193
	Crabs-eyes	277
	Mother-of-Pearl	202
	Pearls	219
	Oyster-shells	236
	Hartshorn	234
	Coral	233
	Oriental Bezoar	108
	Occidental Bezoar	144
	Quick Lime	180
	Slacked Lime	216

These experiments do not sufficiently ascertain the point intended by them: in the first sett, the quantity of acid is too vague and undetermined; in the second, we are not told whether the acid was perfectly saturated; and in both, the acids made use of were so very different from any that can be supposed ever to exist in the human body, that little can be concluded from them with regard to the medical effects of these absorbents. Trial should have been made with the mild vegetable acids, as the juices of certain fruits, four fermented liquors, or rather with four milk. Nevertheless these tables, though not so perfect as could be wished, have their use in the hands of such as can make proper allowances.

ART. III. EARTHS NOT DISSOLUBLE in Acids or other liquors.

These may be ranged in two classes.

Class 1. *Hard crystalline earths*: as the ruby, garnet, emerald, sapphire, hyacinth, and other precious stones; crystal, flint, &c.

THESE kind of substances were introduced into medicine, and many fabulous virtues attributed to them by the superstitious of the earlier ages. Some of them are still preserved in foreign pharmacopœias, but at length very justly expunged from ours, notwithstanding what some late writers of repute speak of their medicinal virtue. These indissoluble hard bodies are not capable of producing any other effect, than by their rigid angular particles (which, though levigated with the utmost care, the microscope still discovers in them) to offend or wound the intestines. In levigation, they wear off so much from the hardest marble instruments, as will equal or exceed their own weight: from this circumstance we may account for their having sometimes appeared to act as absorbents. Some of these stones, exposed to a vehement fire, become in some measure friable; but nevertheless remain indissoluble. Most of the coloured ones by this treatment lose their colour; and in this state prove nearly of the same quality with common crystal: such are, the sapphire, emerald, amethyst, and cornelian. Others melt into a blackish vitreous matter, from which a portion of iron is obtainable by proper fluxes; as the hyacinth and garnet. Geoffroy concludes from hence, that these stones really possess some medical virtues, depending upon their metallic part: but the quantity of metallic matter, sufficient to give them a considerable tinct, is so exceedingly small, and so inclosed in a stony matter not at all soluble by any of the known menstrua, as scarce to admit of any possibility of its acting in the human body.

Class 2. *Softer earths*; the talky, gypseous, and argillaceous.

THE talcs and gypsums have rarely been used as medicines. Some of the former, from their unctuous softness and silver hue, stand recommended externally as cosmetics; and some of the latter, on little better foundation, internally as astringents. But they have long been deservedly rejected by the judicious practitioners. They seem to possess the ill qualities of the alkaline earth (concreting with the mucus of the stomach, &c.), without any of their good ones.

Several of the clays, boles, and terræ sigillatæ, were highly celebrated by the ancients as astringents and alexipharmics, and some of them still continue in esteem; though it is certain they have no great claim to the virtues that have been attributed to them. Their real effects are, to give a greater degree of consistency to the fluids in the first passages, and in some measure defend the solids from their acrimony.

Most of these bodies contain, besides the tenacious indissoluble earth, which is their principal characteristic, (1.) A portion of an earth soluble in acids similar to those of the first section. (2.) Of acid, separable by distillation in a strong fire: this acid is always of the same nature with that obtained from vitriol, sulphur, and alum. (3.) The coloured ones contain likewise small quantities of iron, reducible, by inflammable fluxes, into its metallic form. In consequence of the first of these ingredients, these earths may be looked upon in some measure as absorbent: the acid appears to be united with a part of the absorbent earth into a saline compound, approaching to an aluminous nature; whence they have some degree of astringency:

Glutinous and Unctuous substances. Agency: whether they receive any peculiar virtue from the iron, is greatly to be doubted; since it is in a very crude state, and in quantity extremely small.

These earths unite with water into a turbid liquor, slippery and smooth to the touch, and remain for some time suspended; the sand, grit, or other grosser matters, which are often found naturally mingled with them, subsiding. They may be freed by means of acids from their alkaline earth; by coction in water, from their saline matter; and the coloured ones from their iron by digestion in aqua-regis, the only menstruum we are acquainted with that will extract the ferrugineous matter of argillaceous and bolar earths. This purified, they have all nearly the same appearance and qualities. Exposed to a strong fire, they lose their soft glutinous quality, and are reduced into hard masses, indissoluble as at first.

ART. IV. GLUTINOUS Vegetable and Animal Substances.

Class 1. Vegetable.

Pure gums:	Vegetables abounding with mucilage:
Tragacanth,	Orchis root,
Seneca,	Althaea root,
The gums of cherry, plum, and other European trees.	Quince-seeds, &c.

Gums and mucilages are glutinous vegetable productions, of no particular taste or smell, soluble in water, but not in vinous spirits or in oils. They differ from one another only in degree of tenacity; the more tenacious are called *gums*; those which are less so, *mucilages*. The first naturally exude from certain trees and shrubs; the latter are extracted by art. Almost all vegetable substances contain some portion of these, which, after the refinous part has been extracted by spirit, may be separated from the remaining matter by means of water.

The general virtues of these kinds of substances are, to thicken the fluids, and defend the solids from them when grown sharp or corrosive. Hence their use in a thin acrimonious state of the juices, and where the natural mucus of the intestines is abraded.

Class 2. Animal.

Most animal substances (the fat excepted) contain a viscid matter, in many respects similar to the foregoing, and capable of being extracted by strong coction in water.

Animal glues and gellies have the general qualities of the vegetable gums and mucilages; with this difference, that the former are more nutrimental, and apt to run into a putrid state. Considered as the subjects of chemistry, the difference betwixt them is very great: those of the animal kind are changed by fire into a volatile alkaline salt, and a fetid oil; the vegetable into an acid liquor, and a very small portion of oily matter, considerably less fetid than the former.

ART. V. Soft UNCTUOUS Substances.

Class 1. Insipid vegetable oils; and substances abounding with them; as almonds, and the kernels of most fruits; linseed, and the medullary part of sundry other seeds.

Class 2. Animal fats; as spermæti.

VOL. X. Part II.

UNCTUOUS vegetables unite with water, by trituration, into a milky liquor; and give out their oil upon expression.—These kinds of oils and animal-fats dissolve not in any menstruum except alkaline ones; which change their quality, and reduce them into a soap, dissoluble in water, but more perfectly in vinous spirits; from this compound, the oil may, by a skillful addition of acids, be recovered in a purer state than before, and rendered soluble, like essential oils, in spirit of wine.

The medical virtues of these substances are, to obtund acrimonious humours, and to soften and relax the solids; hence their use internally in tickling coughs, heat of urine, pains, and inflammations; and externally in tension and rigidity of particular parts. The milky solutions, commonly called *emulsions*, though much less emollient than the oils themselves or animal-fats, have this advantage, that they may be given in acute or inflammatory distempers, without danger of the ill consequences which the others might sometimes produce: fats and oils, kept in a degree of heat no greater than that of the human body, soon become rancid and acrimonious; whilst emulsions tend rather to grow sour.

ART. VI. ASTRINGENTS.

Galls,	Balaustines,
Tormentil-root,	Terra Japonica,
Bitroot-root,	Acacia, &c.

ASTRINGENT substances are distinguished by a rough austere taste; and changing solutions of iron, especially those made in the vitriolic acid, of a dark purple or black colour.

Astringents yield their virtues by infusion both to water and vinous spirits, generally in greatest perfection to the former. Oils extract nothing from them; nor do they give over any of their virtue in distillation: nevertheless their astringency is considerably abated by evaporating decoctions of them to the consistence of an extract, and totally destroyed by long keeping.

The medical effects of these kinds of substances are, to constringe the fibres, and incrassate or lightly thicken the juices. Their more experienced use is in disorders proceeding from a debility or flaccid state of the solids; in hæmorrhages, from a thinness of the blood, laxity or rupture of the vessels; in preternatural discharges of other kinds, after the offending matter has been duly corrected or evacuated; and in external relaxations.

In some cases, they produce the effects of astringents; the vessels, constricted and strengthened by them, being enabled to protrude the circulating juices with greater force.

A good deal of caution is requisite in the use of these medicines, especially those of the more powerful kind. In plethoric habits, inveterate obstructions, critical evacuations, and in all kinds of fluxes in general before the morbid matter has been expelled, or where there is any stricture or spasmodic contraction of the vessels, astringents prove eminently hurtful. Where critical dysenteries or diarrhæas are restrained by typtics, the acrimonious matter, now confined in the intestine, corrodes or enflames them; and sometimes occasions a gangrene of the parts.

ART. VII. SWEETS.

Sugar
Honey,Raisins,
Liquorice, &c.

The vegetable sweets are a very numerous tribe; almost every plant that has been examined, disclosing in some of its parts a saccharine juice. The bottoms of flowers, and most kinds of seeds and grain when they begin to vegetate, are remarkably sweet.

Vegetable sweets are extracted both by water and vinous spirits, most readily by the first, but in greatest perfection by the latter. Nothing of their taste arises in distillation with either of these liquors: nevertheless, by long boiling with water they become somewhat less agreeable; but are not much injured by being treated in the same manner with rectified spirit.

The purer sweets, as sugar, promote the union of distilled oils with watery liquors, and prevent the separation of the butyaceous part from milk: from this quality, they are supposed to unite the unctuous part of the food with the animal juices. Hence some have concluded, that they increase fat: others, that they have a contrary effect, by preventing the separation of the unctuous matter which forms the fat from the blood: and others, that they render the juices thicker and more sluggish, retard the circulation and cuticular excretion, and thus bring on a variety of disorders. But sweets have not been found to produce any of these effects in any remarkable degree: common experience shows, that their moderate, and even liberal, use is at least innocent; that they reconcile, not only to the palate, but to the stomach also, substances of themselves disgusting to both; and thus render salutary what would otherwise be injurious to the body.

The unctuous and mucilaginous sweets, as the impure sugars, liquorice, &c. have a considerable degree of emollient and lubricating virtue.—Those accompanied with a manifest acid, as in the juices of most sweet fruits, are remarkably relaxing; and if taken immoderately, occasion diarrhoeas and dysenteries, which sometimes have proved fatal.

ART. VIII. ACIDS.

ACIDS are substances of a penetrating pungency. Applied to the skin, they inflame or exulcerate it: chewed, they occasion a copious discharge of saliva: and snuffed up the nose, they provoke sneezing.

These substances, considered as the subjects of pharmacy, may be divided into three classes,

- Yielding their acrimony {
1. In distillation with water: as horse-radish, mustard, scurvy-grass, &c.
 2. By infusion only: as the greatercelandine, pyrethrum, &c.
 3. Neither to infusion, nor distillation: as arum and dracunculus.

The general effects of acid medicines are, to stimulate the vessels, and dissolve tenacious juices. In cold leucoplegmatic habits, stagnations of the fluids, and where the contractile power of the solids is weak, they prove powerful expectorants, deobstruents, diuretics, and emmenagogues; and if the patient is kept warm, sudorifics. In hot bilious constitutions, plethoric habits, inflammatory distempers, where there is al-

ready a degree of irritation, where the juices are too Aromatics and Bitters. thin or acrimonious, or the viscera unbound, these stimulating medicines prove highly prejudicial, and never fail to aggravate the disease.

Certain acid substances have been lately recommended in dry convulsive asthma: of the efficacy of the squill in particular, for the cure of this disorder, several instances are related in the *Commercium Literarium* of Norimberg for the years 1737 and 1739. Cartheuser thinks, that not the asthma itself, but a particular effect of it, was removed by this medicine. He observes, that in all asthmas the free circulation of the blood through the pulmonary vessels is impeded; and hence, during every paroxysm, the lungs are in a kind of oedematous state: that if this oedema, becoming habitual, remains after the fit is over, it is either perpetually occasioning fresh ones, or gives rise to a dropsy of the breast: that acid medicines, by removing the oedema, remove what was originally an effect of the asthma, and in time a cause of its aggravation.

ART. IX. AROMATICS.

AROMATICS are substances of a warm pungent taste, and a more or less fragrant smell. Some of the spices are purely aromatic, as cubebæ, pepper, cloves; some substances have a sweetness mixed with the aromatic matter, as angelica-root, aniseed, fennel-seed; some an astringency, as cinnamon; some a strong mucilage, as cassia lignea; some a bitterness, as orange-peel. The aromatic matter itself, contained in different subjects, differs also not a little in its pharmaceutical properties. It is extracted from all by rectified spirit of wine; from some in great part, from others scarcely at all, by water. The aromatic matter of some subjects, as of lemon-peel, rises wholly in distillation both with spirit and water; that of others, as cinnamon, rises wholly with water, but scarcely at all with spirit; while that of others, as pepper, is in part left behind after the distillation of water itself from the spice.

With regard to the general virtues of aromatics, they warm the stomach, and by degrees the whole habit; raise the pulse, and quicken the circulation. In cold languid cases, plegmatic habits, and a weak flaccid state of the solids, they support the vis vite, and promote the salutary secretions. In hot bilious temperaments, plethoric habits, inflammatory indispositions, dryness and strictures of the fibres, they are generally hurtful.

ART. X. BITTERS.

Gentian root,	Lesser centaury,
Hops,	Carduus, &c.

BITTERS for the most part yield their virtue both to watery and spirituous menstrua; some more perfectly to one, and others to the other. None of the substances of this class give over any thing considerable of their taste in distillation, either to water or to spirit; their bitterness remaining entire, and frequently improved, in the extracts. Such as are accompanied with flavour, as wormwood, may by this process be reduced into simple flavourless bitters.

These substances participate of the virtues of astringents and aromatics. Their general effects are, to constringe the fibres of the stomach and intestines, to warm the habit, attenuate the bile and juices in the

Emetics
and Cathar-
tics.

first passages, and promote the natural evacuations, particularly of sweat and urine. In weakness of the stomach, loss of appetite, indigestion, and the like disorders, proceeding from a laxity of the solids, or cold sluggish indispotion of the juices, these kinds of medicines do good service. Where the fibres are already too tense and rigid, where there is any immoderate heat or inflammation, bitters very sensibly increase the distemper; and, if their use is continued, communicate it to the kidneys: hence the urine becomes high-coloured, small in quantity, and at length suppressed; a dropy soon succeeding. If the kidneys were before so lax as to remain now uninjured, yet the other viscera become gradually more and more rigid, and a tabes is at length brought on.

Bitter substances destroy insects, and prevent putrefaction. Hence they are recommended as anthelmintic, and externally as antiseptics.

ART. XI. EMETICS AND CATHARTICS.

Hellebore,	Colocynth,
Julip,	Scammony,
Ipecacuanha,	Gamboge, &c.

These substances consist of a resinous part, in which the purgative or emetic quality resides: and a gummy saline one, which acts chiefly as a diuretic. The first is extracted or dissolved by vinous spirits; the latter by water. Nothing arises in distillation from either.

The acrid resins, exhibited by themselves, tenaciously adhere to the coats of the intestines, by their stimulating power irritate and inflame them, and thus produce sundry violent disorders. Hoffman relates, that he has sometimes observed convulsions, and a paralysis of both sides, from their use.

These inconveniences may be avoided, by previously triturating them with substances capable of dividing their tenacious texture, and preventing their adhesion; by this means they become mild and safe, operate without disturbance, and at the same time

more effectually answer the purposes intended by them.

Some have endeavoured to correct the ill quality of the resinous purgatives, by the addition of acids and aromatic oils. Acids weaken their power, but have no other effect than what a diminution of the dose would equally answer. The pungent essential oils may serve to warm the stomach, make the medicine sit easier, and thus prevent the nausea which sometimes happens; but as soon as the resin begins to exert itself in the intestines, these oils, instead of correcting, increase its virulence; being themselves apt to occasion the inconveniences which they are here intended to prevent, an irritation and inflammation of the bowels. Alkaline salts or soaps have a better effect; as they dispose the resin to solution, and promote its operation.

The medicines of this class seem to act by liquefying the juices, and stimulating the coats of the stomach and intestines. If the irritation is strong and sudden, their action is quick and upwards: if slower, downwards. Cathartics given in a liquid form, or in very sensible habits, often prove emetic; and emetics, where mucus abounds, cathartic. They operate more violently in robust constitutions than in those of a contrary temperament; the vessels being in the former more tense and rigid, and consequently less capable of bearing an equal degree of irritation.

The action of these medicines is extended beyond the prime viæ: This appears evident from the increase of the pulse which always accompanies their operation; and from the common observation of children being purged by the milk, if the nurse has taken a cathartic. Some of them, particularly hellebore, are said to purge, if only applied externally in issue.—Purgatives, even of the more powerful kind, exhibited in suitable small doses, in conjunction with the milder aperients, may be introduced into the habit, so as to prove notable deobstruents, diuretics, and diaphoretics, without acting sensibly by stool.

A CATALOGUE of the SIMPLES used in the MATERIA MEDICA, exhibiting at one view their TECHNICAL NAMES, ENGLISH NAMES, PARTS USED IN MEDICINE, VIRTUES, and the different PREPARATIONS FROM THEM.—A particular account of the different articles of this list is given in the course of the alphabet, chiefly under the Linnæan names: And the method of making the preparations from them are shown under the article PHARMACY. The notes subjoined at the bottom of the following pages are intended to supply some particulars relating to a few of the detached articles already past.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Abies ruber (<i>Pinus abies</i> , Lin.)	The fir-tree.	The wood, tops, and cones.	Diuretic and diaphoretic.	A decoction.
Abrotanum femina (<i>Santolin chama-cypar</i> , Lin.)	Lavender cotton.	The leaves.	Stimulant, detergent, and anthelmintic.	Decoction, and ointment for cutaneous eruptions.
Abrotanum mas (<i>Artemisia abrotanum</i> , Lin.)	Southernwood.	The leaves.	Stimulant, detergent, aperient, and sudorific.	Decoction and tincture; also lotion and ointment for cutaneous eruptions.
Abinthium maritimum (<i>Artemisia maritima</i> , Lin.)	Sea wormwood.	The tops.	Stomachic.	An oil, extract, conserve, and several distilled tincture-waters. They also enter the common fomentation and green oil.
Abinthium vulgare (<i>Artemisia absinthium</i> , Lin.)	Common worm-wood.	The leaves and flowering tops.	Stomachic.	

List of
Simples.

List of
Simples.

TECHNICAL NAMES. ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Acacia Germanica The floc. (<i>Prunus spinosa</i> , Lin.)	Inspissated juice.	Astringent.	
Acacia vera (<i>Mimosanilatica</i> , Lin.)	Inspissated juice.	Astringent.	
Acetofa (<i>Rumex acetof.</i> Lin.)	Leaves.	Astringent and antiscorbutic.	An effential salt for taking out spots in clothes. A decoction.
Acetofella (<i>Oxalis acetofel.</i> Lin.)	The leaves.	Astringent and antiscorbutic.	A conserve.
Acetum. Vinegar.		Cordial, refrigerant, sudorific, and antiseptic.	A distilled spirit.
Aconitum (<i>A. napellus</i> , Lin.)	The herb and leaves.	Narcotic.	Tincture.
Acorus. See <i>Callamus arom.</i> infra.			
Adiantum verum Maiden-hair. (<i>Adiant. capill. Ven.</i> Lin.)	The leaves.	Attenuating and aperient.	Decoction and syrup; its virtues best obtained from an infusion of the herb sweetened with sugar and liquorice, and drank as tea.
Aer dephlogisticus. Dephlogisticated air.		Supposed to be antiseptic and corroborative.	
Aer mephiticus. Fixed air.		Antiseptic and lithontriptic.	
Aer nitrosus. Nitrous air.		Very antiseptic.	
Æs. See <i>Cuprum</i> . Brass. See <i>Copper</i> .			
Agaricus, (<i>Boletus pini larici</i> , Lin.)	Agaric.	Cathartic.	An aqueous extract, but now much disused.
Agaricus chirurgorum (<i>Boletus ignarius</i> , Lin.)	Female agaric, or agaric of the oak, touchwood, or spunk.	Styptic.	Pieces applied externally.
Agnus castus (<i>Vitex agnus castus</i> , Lin.)	The chaste tree.	Antaphrodisiac.	
Agrimonia (<i>A. eupatoria</i> Lin.)	Agrimony.	Attenuant and tonic.	Digested in whey, it forms a diet-drink used by some in the spring.
Albumen ovi. White of an egg.		Discutient.	
Alchemilla (<i>A. vulgaris</i> , Lin.)	Ladies-mantle.	Astringent.	
Alkekengi, (<i>Physalis alkekengi</i> , Lin.)	Winter-cherry.	Aperient and diuretic.	Dried and powdered. Inspissated juice.
Alliaria (<i>Erythimum alliaria</i> , Lin.)	Sauce-alone, or Jack-by-the-hedge.	Sudorific and deobstruent.	
Allium (<i>A. sativum</i> , Lin.)	Garlic.	Stimulant, attenuant, discutient, and diuretic.	A syrup and oxymel, ointment and poultice.
Alnus (<i>Betula alnus</i> , Lin.)	Alder.	Astringent.	Decoction. The leaves chopt and heated, efficacious for dispersing milk in the breasts.
Aloes (<i>Aloe perfoliata</i> , Lin.)	Aloes.	Cathartic.	Ingredient in several tinctures and pills.
Alfina (<i>A. med.</i> Lin.)	Chickweed.	Refrigerant.	

List of Simples.	TECHNICAL NAMES. ENGLISH NAMES.		PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.	List of Simples.
	Althea (<i>A. officina- lis</i> , Lin.)	Marshmallow.	The leaf and root.	Emollient.	A syrup and ointment.	
	Alumena.	Alum.	The whole.	Strongly astringent.	A styptic powder, styptic wa- ter, whey, &c.	
	Ambragrisea.	Ambergrise.	The whole.	A high cordial.	A tincture or essence.	
	Ammi vulgaris.	Bishop's weed.	The leaves.	Stimulant.	An ingredient in the theriaca.	
	Amomum verum.	True amomum.	The seeds.	Aromatic.	An ingredient in the theriaca.	
	Amomum vulgare (<i>Sison</i> , Lin.)	Bastard stone-par- sley.	The seeds.	Carminative and diuretic.		
	Ammoniacum. See Gummi.					
	Amygdala (<i>Am. con.</i> Lin.)	Sweet and bitter al- monds.	The fruit.	Relaxing.	Expressed oil and emulsion.	
	Amylum.	Starch.		Astringent.		
	Anacardium occi- dentale, (Lin.)	Cashew-tree.	The nuts.	Corrosive.	Oil outside, but the kernels used as almonds; the gum instead of gum arabic.	
	Anagallis (<i>Arven- sis</i> , Lin.)	Pimpernel.	The leaves.	Sudorific and nerve- vine.	Extract, or inspissated juice.	
	Ananas (<i>Bromelia ananas</i> , Lin.)	The pine-apple.	The fruit.	Refrigerant.		
	Anchusa (<i>A. tinc- toria</i> , Lin.)	Alkanet.	The root.	Only used for its colour.		
	Anethum (<i>A. gra- veolens</i> , Lin.)	Dill.	The seeds.	Carminative.	Distilled oil, water, and spi- rituous extract.	
	Angelica (<i>A. Arch- angelica</i> , and <i>syl- vestris</i> , Lin.)	Angelica.	The roots, stalks, leaves, and seeds.	Aromatic.	Several compound waters.	
	Angusturæ cor- tex, (A)					
	Anisum (<i>Pimpin- ella anisum</i> , Lin.)	Anise.	The seed.	Aromatic and to- nic.	An essential oil, a spirituous compound water, &c.	
	Antimonium.	Antimony.		Diaphoretic, cat- hartic, emetic, or caustic.	A number of chemical prepa- rations. See CHEMISTRY- Index, KERMES Mineral, and REGULUS of Antimony.	
	Aparine (<i>Gallium aparine</i> , Lin.)	Goosegrass, or cli- vers.	The leaves.	Aperient.		
	Apium (<i>A. gra- veol.</i> Lin.)	Smallage.	The roots, leaves, and seeds.	Carminative.	Diet-drinks.	
	Aqua marina.	Sea-water.		Cathartic and alte- rative.		
	Aquæ minerales.	Mineral waters.		Tonic and altera- tive.		
	Aquæ sulphuræ.	Sulphureous wa- ters.		Alterative and au- thelmintic.		
	Argentina (<i>Po- tentilla argentin.</i> Lin.)	Silverweed.	The leaves.	Corroborant.		
	Argentum vivum.	Quicksilver.		A most powerful alterant.	Several chemical prepa- rations; see CHEMISTRY- Index. An ingredient in se- veral other official prepa- rations.	

Aristo-

Aristo-

(A) The Angustura bark was first imported from the West Indies in 1788; but it is a native of Africa. Mr Bruce, who had been cured of a dysentery in Abyssinia by the bark of a plant called there *Wogginas*, brought the seeds from that country, and the plant is now cultivated in Kew garden and other places under the name of *Brucea antidyenteria*, or *ferruginea*. He supposed the bark of this was the same with that of the Angustura; but Dr Duncan, in the Medical Commentaries for 1790, says that they are totally different when compared together. For an account of the Angustura bark, see *Jesuit's Bark*.

	<i>Aparagus</i> (<i>A. officinalis</i> , Lin.)	Alparagus.	The roots.	Supposed diuretic, but uncertain.	
	<i>Aperula</i> .	Woodruff.	The flowers.	Attenuant and aperient.	

Asphodelus,

(b) This pernicious mineral has some time ago been introduced into medicine as a certain remedy for cancers; but Mr Justamond, who published a treatise on this subject two or three years ago, informs us, that even the most guarded use of it in the external way, while it produces the happiest effects in healing cancerous ulcers, yet occasions such disagreeable symptoms of the paralytic kind, that it cannot be perfited in. The latest trials in London are likewise said to confirm this account; notwithstanding which, however, the internal use of it has since gained ground in a variety of disorders, particularly in intermitting fevers, which are said to be readily cured by it sometimes after the bark and all other remedies had failed. A solution of the mineral is given by drops, from one sixteenth to a sixth part of a grain for a dose, largely diluted in a warm aqueous liquid. Dr Aikin recommends oil and milk as a certain remedy against this destructive poison. He quotes from Hoffman an instance where several persons of distinction had tasted food mixed with arsenic instead of sugar. All of them were seized with anxiety at the breast, pain at the stomach, tremor of the lips, and reachings. Milk and oil were given in great plenty, and they continued strongly vomiting for half a day. Some vomited no less than 100 times; but all of them recovered. Some instances of a similar kind have come within the Doctor's own knowledge. Sage in his Mineralogy relates, that the regulus is much less dangerous than the calx or glafs: he says that on giving half an ounce to a cat, the animal only grew meagre for some time, but afterwards became fat again. He says that acids, particularly vinegar, are the antidotes to this poison; and that oils and emulsions do not so effectually obtund this poison as acids do. Of this he has had experience in brutes. He adds, that the regulus is not soluble in water, and that the founders are more afraid of fumes of lead than arsenic.

(c) Dr Aikin informs us, that the insupportable pungeny on the tongue, which has hitherto prevented it from being used in a fresh state so as to exert its full virtues, is effectually covered by unctuous and gummy materials. The fresh root beaten into a smooth mass, with the addition of a little testaceous powder which promotes the division of it, may be either mixed with about an equal quantity of powdered gum arabic, and three or four times as much conserve, so as to make them into an electuary; or rubbed with a thick mixture of mucilage of gum arabic and spermaceti, gradually adding any suitable watery liquors, and a little syrup in order to form an emulsion, two parts of the root, two of gum, and one of spermaceti, make an emulsion, which scarce impresses any degree of pungeny upon the tongue though kept long in the mouth. In these forms our author has given the fresh root from ten grains to more than a scruple, three or four times a-day: it generally occasioned a slight sensation of warmth, first about the stomach and then in the remoter parts; manifestly promoted perspiration, and frequently produced a plentiful sweat. Several obstinate rheumatic pains have been removed by the use of this preparation, which our author therefore recommends to further trial.

(d) The leaves of this plant are by some supposed to be more powerful than the roots as emetics and cathartics, but they are milder as errhines. Geoffroy relates, that a single dose of the errhine of which this root is an ingredient has occasioned a discharge for three days; and that he has known a palsy of the mouth and tongue cured by the same means. He recommends it in stubborn disorders of the head proceeding from viscid matters, in palsies, and lethargic distempers. During its operation the patient must carefully avoid cold; which is apt to produce pultules, inflammations, swellings of the face, and sometimes worse symptoms than even these. The empirical herb-snuffs have the leaves of afarum for their basis, but sometimes mixed with ingredients of a more dangerous nature.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
<i>Aphodelus</i> , (<i>A. Aphodel</i> , or king's <i>peplus</i> , Lin.)	pear.	The roots.	Emollient and suppurative.	
<i>Atriplex</i> (<i>Cheopodium vulvar</i> , Lin.)	Stinking orach.	The leaves.	Antispasmodic.	A spirituous tincture, decoction, or conserve, recommended by Tournefort and others.
<i>Avena fativa</i> (Lin.)	Oats.	The grain.	Emollient.	Decoction.
<i>Aura electrica</i> .	Electricity.		A violent stimulant.	
<i>Aurantium</i> (<i>Citrus aurant</i> , Lin.)	The orange.	The leaves, fruit, and flowers.	Cordial, stomachic, and refrigerant.	An essential oil, a distilled water, and a conserve.
<i>Auricula</i> Judæ, Jews-ears. (<i>Tremell. verruc</i> , Lin.)		The whole.	Purgative, or astringent; uncertain.	
<i>Auripigmentum</i> .	Orpiment.		Corrosive, but less so than arsenic.	
<i>Axungia porcina</i> .	Hog's lard. }		Emollient.	
<i>Axungia viperina</i> .	Viper's fat. }			
<i>Balaustia</i> (<i>Punica granat</i> , Lin.)	Balaustine, or double-flowered pomegranate tree.	The flowers.	Astringent.	Ingredient in a powder.
<i>Balsamita</i> (<i>Tanacetum balsaminum</i> , Lin.)	Costmary.	The leaves.	Aromatic, antihysteric.	Distilled water and spirituous tincture.
<i>Balsamum Canadense</i> (<i>Pinus balsamea</i> , Lin.)	Balsam of Canada.	The rosin.	Diuretic and tonic.	
<i>Balsamum Copayve</i> (<i>Copaifera officinalis</i> , Lin.)	Balsam of Copivi.	The rosin.	Diuretic and tonic.	An empyreumatic oil, and an ingredient in some tinctures (z).
<i>Balsamum Gileadense</i> (<i>Amyris Gileadensis</i> , Lin.)	Opobalsam, or balm of Gilead.	The rosin.	Said to be a most extraordinary vulnerary.	
<i>Balsamum Peruvianum</i> (<i>Myroxylon peruiferum</i> , Lin.)	Balsam of Peru.	The rosin.	A fine warm aromatic.	An ingredient in many tinctures, and some ointments.
<i>Balsamum Toluianum</i> (<i>Toluifera balsaminum</i> , Lin.)	Balsam of Tolu.	The rosin.	Aromatic and corroborant.	An ingredient in several tinctures, elixirs, and a kind of pectoral pills.
<i>Bardana</i> major, (<i>Arctium lappa</i> , Lin.)	Burdock.	The roots and seeds.	Aperient, diuretic, and sudorific.	Decoction.
<i>Barytes</i> (r).				

Beccabunga,

(z) Balsam of Copivi has been employed empirically in hemorrhoidal cases; and Dr Cullen informs us, that he has known it give relief in such cases, in doses from 20 to 40 drops once or twice a day, mixed with powdered sugar. Fuller recommends it in consumptions; but his practice is censured by Dr Fothergill in the 4th volume of London Medical Observations.

(r) *Barytes*. The solution of the aerated barytes, or terra ponderosa, in spirit of salt, has been found capable of producing powerful effects on the human system. Several trials of it were made in the year 1789 by Dr Crawford, in St Thomas's hospital; and it was found to be very efficacious in scrophulous complaints. — In some cases of swelled glands, foul ulcers, enlarged joints, and general cachexy, singular relief was given by the muriated barytes, either alone or joined with mercurials, antimonials, and the bark. The medicine in a few cases appeared to augment the cuticular secretion; in most it occasioned an uncommon flow of urine, and almost universally improved the appetite and general health of the body. Few stomachs, however, could bear more than from six to ten drops of a saturated solution, nor did a continued use of the medicine reconcile the stomach to it, but rather the contrary. Sometimes it produced a vertigo, which probably arose from its nauseating quality. Dr Crawford is of opinion, that this solution, when injudiciously managed, is capable of producing deleterious effects, by disordering the nervous system, and bringing on violent vomiting and purging; From some experiments made upon dogs, it appears that a large dose would prove fatal.

Caryophyllum (C. <i>aromaticus</i> , Lin.)	The clove-tree.	The flower-cups.	Strongly aromatic.	An essential oil. Ingredient also in many official compositions
Cascarilla (C. <i>cafar</i> , Lin. <i>Croton eluteria</i> , Swartz Prodr.)	Cascarilla.	The bark.	Aromatic and stimulant.	Infusions.
Cassia fistularis (C. <i>stula</i> , Lin.)	Cassia.	The fruit.	Purgative.	An ingredient in two electuaries.
Cassia lignea (L. <i>rus cassia</i> , Lin.)	Cassia.	The bark and flower-buds.	Aromatic.	The basis of a distilled water.
Cassumunar.	Cassumar.	The root.	Stomachic and carminative.	
Castoreum (C. <i>stor fiber</i> , Lin.)	Castor.		Nervine and antispasmodic.	A simple water; a spirituous water; a tincture. Ingredient in several official compositions.
Catechu (M. <i>sa catechu</i> , Lin.)	Catechu, <i>vulgo</i> Japan earth.		Astringent.	A tincture, troches, and confection, and an ingredient in several official compositions.
Celery (A. <i>graculens</i> , Lin.)	Celery.	The leaves.	Laxative.	
Centaurium majus (C. <i>tauracentauryum</i> , Lin.)	Greater centaury.	The root.	Astringent, aperient, and vulnerary.	
Centaurium minus (C. <i>tiana centaury</i> , Lin.)	Lesser centaury.	The tops.	Stomachic.	Tincture and infusion.
Cepa (A. <i>um cepa</i> , Lin.)	The onion.	The root.	Attenuating and diuretic.	
Cera alba.	White wax.		Emollient.	Ingredient in many plasters and ointments.
Cera flava.	Yellow wax.		Emollient.	Ingredient in almost all ointments.
Cerasus (P. <i>rus cerasus</i> , Lin.)	The cherry tree.	The fruit and gum.	Refrigerant; the gum partaking of the properties of gum-arabic.	
Cerefolium (S. <i>andis cerefol</i> , Lin.)	Chervil.	The juice.	Aperient and diuretic.	
Ceterach (A. <i>plen-ceterach</i> , Lin.)	Spleenwort.	The leaves.	Diuretic (g).	
Cevadilla (V. <i>eratrum album</i> , Lin. ?)	Indian caustic barley.	The seeds.	Virulently caustic, (h).	
Chamaedrys (T. <i>crium chamaedr</i> , Lin.)	Germander.	The leaves and tops with the seed.	Sudorific, diuretic, &c.	

Chamæmelum

(c) M. Morand relates, that these leaves have lately been discovered to have an admirable diuretic virtue; that they were used with great success by Count d'Auteuil, a Spanish naval commander, for the gravel, with which he was violently tormented; and since that time they have come greatly into use at Paris, Verdun, and Grenoble. From observations made in those places it appears, that they carry off sand, cleanse the kidneys, and mitigate pains in the urinary passages; that the method of using them is to drink infusions of the leaves in the morning at tea, adding such other medicines as may be judged proper.

(h) These seeds appear to be the strongest of all vegetable caustics. Monardes relates, that in putrid ven-

minous.

	Ciccer (<i>C. arietin.</i> Lin.)	Redchices, or chick peas.	The seeds.	Lithontripic and diuretic, but very doubtful.		
	Cichorium (<i>C. in- tyb.</i> Lin.)	Wild succory.	The roots and leaves.	Laxative and anti- scorbutic.		
	Cicuta major (<i>Co- nium maculat.</i> Lin.)	Hemlock (†).	The leaves and seeds.	Resolvent and alte- rant.	Inspissated juice of the leaves, and an extract from the seeds.	

minous ulcers and gangrenes, they have the same effects as corrosive sublimate, or the actual cautery; and that the way of using them is to sprinkle a little of powdered seed upon the part; or, for the greater safety, to dilute it with watery liquors, and apply lint dipped in the mixture. In the *Amanitates Academicæ* of Linneus, they are said to be the most powerful of all medicines for destroying cutaneous insects in children.

(†) It is supposed that the juice of this plant was the poison so much used among the Athenians for putting criminals to death; but from some late experiments this seems to be doubtful; or at least that the remedy is very easy. Mr Haram, apothecary at Chartres, informs us, that a large spoonful of the juice given to a cat had no sensible effect; a second produced a visible *embarras* on the region of the reins: in a little time the animal staggered, but did not fall. A quarter of an hour after, she was found stretched out motionless, with her paws rigid. Half a drachm of theriaca, with two large spoonfuls of wine, were given without effect: but no sooner was a large spoonful of lemon-juice swallowed than she got up as if nothing had happened, and continued afterwards in good health. Other authors likewise inform us, that vinegar is an antidote against the poisonous effects of this plant.

With regard to its medical virtues, Dr Monro, who has seen it tried in a great number of cases, informs us, that he never saw it cure a confirmed cancer, whether ulcerated or not; that in a few cases of ulcerated cancers it mended the discharge, and changed it from a thin ichor to an appearance of laudable pus; but, notwithstanding this favourable appearance, the distemper at last terminated fatally.—In scrophulous cases, some few small tumours were thought to be dissolved by it; but large hard swellings were never removed by it, tho' the remedy was continued for weeks and months. The discharge from scrophulous fores of the extremities, however, was often mended by it; and in many cases, it was found to be of more service when joined with the bark than when given alone: the action of the bark and mercury was thought to be rendered more powerful by it. In the chincoough it did not produce any remarkable effects. In some few instances, he imagined that it hurt the health of the patients; and in one or two, that it hastened death. In this last case, indeed, the use of the cicuta had been laid aside for some time, and the patients sunk so gradually, that our author was in doubt what might have been the cause of their death.

The roots of hemlock have been supposed to be more active than the leaves, both when taken internally and when outwardly applied. Dr Storck relates, that on being cut, it yields a bitter acrid milk, of which a drop or two applied to the tip of the tongue occasioned a rigidity, pain, and swelling of the part, so as to deprive him of the power of speech. These symptoms, however, disappeared on washing the part with citron juice. When dried, it loses its virulence; so that Dr Storck says, he has taken a grain or two of the powder without injury. Other authors give instances where 20 and 30 grains have been given with good effect in schirrosities of the liver, quartan agues, on the approach of a fit, and even in acute fevers. Dr Aikin informs us, that the fresh root seems not to be at all times of equal virulence; and that he has seen it chewed freely without

	<i>Coccinella</i> (<i>Coccus</i> <i>cacti</i> , Lin.)	Cochineal.		Sudorific, but chief- ly used for co- louring.		
	<i>Cocculus Indicus</i> , (<i>Menisperm. co-</i> <i>cul.</i> Lin.)	Indian berry.	The fruit.	Narcotic.		
	<i>Cochlearia</i> (<i>C. of-</i> <i>ficialis</i> , Lin.)	Scurvy-grass.	The leaves.	Stimulating and attenuant.	A conserve and spirit. An in- gredient in some other offi- cial preparations.	
	<i>Coffea</i> (<i>C. Arabica</i> , Lin.)	The coffee-tree.	The fruit.	Stomachic and cor- roborant.	A decoction.	
	<i>Colchicum</i> (<i>C. au-</i> <i>tumnale</i> , Lin.)	Meadow saffron.	The root.	Diuretic.	A syrup and oxymel.	
	<i>Colocynthis</i> (<i>Cucu-</i> <i>mis colocynthis</i> , Lin.)	Coloquintida, or bitter-apple.	The medullary part of the dried fruit.	Violently cathartic.	An ingredient in some cathar- tic pills and extracts.	
	<i>Columbo</i> (<i>Ignatia</i> <i>amara</i> , Lin.)	Columbo, or Co- lomba.	The root.	A most excellent antiseptic and stomachic.	A vinous tincture.	
	<i>Conessi</i> (<i>Nerium</i> <i>antidysentericum</i> , Lin.)	Conessi.	The bark.	Antiseptic and tonic (λ).		
	<i>Consolida major</i> , (<i>Symphitum offi-</i> <i>cin.</i> Lin.)	Comfrey.	The root.	Emollient.		

Contrayerva

without any other effect than that sweetishness observable in parsley roots or carrots. There are likewise instances, where the cicuta roots have been taken to the quantity of some drachms, or even ounces, without any bad consequence.

The seeds have been recommended as demulcent, pargoric, and antaphrodisiac; but little more (according to Dr Aikin) is yet known about them, but that they are innocent to some birds. Mr Ray says, that he found the crop of a thrush full of them, and that at a season when the corn was in full growth.

In the first volume of the Medical Commentaries, an extract prepared from hemlock-seeds is preferred to that made from the leaves; and in the last Edinburgh Pharmacopoeia, an extract of this kind is ordered as an official.

(κ) Dr Aikin informs us, that the expressed juice of the leaves has sometimes proved successful in dropries, when other remedies had failed. For this purpose it is not depurated, but only freed by passing through a strainer from the grosser feculencies, and mixed with an equal quantity of white wine; three or four spoonfuls to be taken every morning and evening.—The following decoction (as we are informed by Dr Monro) was long kept a secret by a person at Andover, and is said to have carried off the water from several people labouring under a dropfy. Take of artichoke leaves and stalks three handfuls; of bruised juniper-berries one quart; of scraped horse-raddish one handful; of green fir-tops two handfuls; of bruised white mustard-seed two table-spoonfuls; mix the whole, and boil them in two gallons of water to one, and strain the whole thro' a cloth. Half a pint to be taken by a grown person morning and evening, adding a little syrup or sugar to make it agreeable.

(λ) This bark is reckoned a specific in diarrhœas; the fine powder being made use of in an electuary formed with syrup of oranges, and given to the quantity of half a drachm or more four times a day, after a vomit has been given. The first day it is taken, the number of stools is generally increased, without any increase of the griping; the second, the colour of the stools is meliorated; and, on the third or fourth, the consistence approaches to the natural, when it makes a cure. It seldom fails in curing a recent diarrhœa, proceeding from irregularities in diet without fever; and it is frequently of service in habitual diarrhœas.

<i>Hypericum</i> (H. perforatum, Lin.)	St John's wort.	The leaves, flowers, and feeds.	Diuretic, sudorific, and alterant.	Gives name to a coloured oil.
<i>Hypocistis</i> (Cytisus hypocist. Lin.)	Hypocistis.	The juice.	Astringent.	Juice inspissated.
<i>Hyssopus</i> (H. officinalis, Lin.)	Hyssop.	The leaves.	Aromatic and pectoral.	A distilled water.
<i>Jalappa</i> (Convolvulus jalappa, Lin.)	Jalap.	The root.	Cathartic.	An extract, a simple tincture, a compound tincture, a resin, and powder.
<i>Japonica terra</i> . See <i>Catechu</i> , supra.				
<i>Imperatoria</i> (I. officinalis, Lin.)	Mafter-wort.	The root.	Aromatic.	
<i>Indian root</i> . See <i>Radix Indica</i> , infra.				
<i>Ipecacuanha</i> (Ptychotria emetica, Lin.)	Ipecacuanha.	The root (n.)	Emetic and cathartic.	A vinous tincture, and a powder.

Iris

(n) A root has been sometimes imported, under the name of white ipecacuanha (*viola ipecacuanha*, Lin.), which has little or nothing of the virtues of the true kind. More dangerous abuses, however, have been practised by the substitution or mixture of the roots of a kind of *apocynum*, which have been found to operate with great violence both upwards and downwards, so as to prove fatal in some cases. They may, however, easily be distinguished by their colour, which is a deep reddish yellow, while the true ipecacuanha is pale coloured or greyish: the poisonous roots are likewise larger, the fissures more distant, and the intermediate spaces smoother, than in the true ipecacuanha. This root is found to increase the purgative virtue of jalap remarkably. Dr Aikin informs us, that 15 grains of jalap, with two or three of ipecacuanha, purge more than twice the quantity of jalap by itself.

"Of late (says Dr Monro), a notion has prevailed, that the keeping up a nausea by means of small doses of ipecacuanha, or of watery solution of emetic tartar, was of great service in promoting the cure of fevers, as well as of fluxes, from a belief that they affected the nervous system, and were capable of exciting the action of the extreme vessels, and of increasing the secretions by the skin, and of the internal organs. Hitherto I have not found this method to answer my expectations; and I have always observed, that such a dose of an emetic as emptied the stomach freely, and gave a shake to the whole frame, had a much better effect than

	Limon, (<i>Citrus me- dica</i> , Lin.)	The lemon-tree.	The fruit.	Aromatic, antiscor- butic, and cordial.	An essential oil; an ingredi- ent in several compositions.	
	Linaria (<i>Antirrhini- num linaria</i> , Lin.)	Toad-flax.	The leaves.	Diuretic and ca- thartic, but doubtful.		
	Lingua cervina, (<i>Asplenium scolopend.</i> Lin.)	Hart's tongue.	The leaves.	Aperient.		
	Linum catharticum (<i>Euphorbia lathy- rus</i> , Lin.)	Purging flax.	The leaves.	Cathartic.	Infusion in whey. Dried powder.	
	Linum Sativum Flax. (<i>L. usitatissimum</i> , Lin.)		The seed.	Emollient.	An expressed oil. Cataplasma.	
	Liquida ambra (<i>a- cernegundo</i> , Lin.)	Sweet gum, or stor- rax tree.	The resinous juice.	Aromatic and cor- dial.		
	Lithospermum (<i>L.</i> Gromwell. <i>officinale</i> , Lin.)		The seeds.	Resolvent; lithon- triptic.		
	Lobelia (<i>L. sp. hilti- ca</i> , Lin.)	Blue cardinal flower.	The root (o).	Alterant, and deter- gent.	Decoction.	
	Lujula, or wood- sorrel. See <i>Ace- tosella</i> , supra.					
	Lumbrici et limaces terrestres.	Earth worms and snails.		Aperient and ana- leptic.	Decoction in milk.	
	Lupinus (<i>L. albus</i> , Lin.)	White lupines.	The seeds.	Anthelmintic.		
	Lupulus (<i>Humul.</i> <i>lup.</i> Lin.)	Hops.	The loose leafy heads which grow upon the tops of the stalks.	Diuretic and stoma- chic.		

Lycoperdon

(o) This root was long a famous secret among the North American Indians for curing the venereal disease. The secret was purchased by Sir William Johnson, and has been published in the writings of Bartram, Kalm, &c. The following method of using it is, by Dr Aikin, recommended as the best: "A decoction is made of an handful of the roots in three measures of water. Of this half a measure is taken in the morning fasting, and repeated in the evening; and the dose is gradually increased till its purgative effect becomes too violent, when the medicine is for a time to be intermitted, and then renewed till a perfect cure is effected. One dose daily is sufficient during the latter part of the treatment; and the regimen, during the whole process, is to be equally strict with that observed in a course of mercurial salivation. From the third day, the ulcers are to be well washed twice daily with the decoction; and it is said, that when they are very deep and foul, the Indians sprinkle them with powder of the internal bark of the spruce tree. By this method we are assured that inveterate venereal complaints are cured without the aid of mercury."

	<i>Melissa</i> (<i>M. officin.</i> Lin.)	Balm.	The leaves.	Aromatic.	An essential oil, and an in- fusion.	
	<i>Melo</i> (<i>Cucumis melo</i> , Lin.)	The melon.	The seeds.	Refrigerant and emollient.		
	<i>Mentha crispata</i> (Lin.)	Danish or German curled mint.	The herb.	Aromatic and cor- dial,	A distilled water, essential oil, and essence. An ingredient in several official prepara- tions.	
	<i>Mentha vulgaris</i> , (<i>M. viridis</i> , Lin.)	Spearmint.	The herb.	Aromatic and cor- dial.	A distilled water, an essential oil, a spirit, and essence. An ingredient in several official preparations.	

Mentha

(p) The juices of horehound and plantain mixed are remedies of great repute in America against the bite of the rattlesnake. They are given by spoonfuls at short intervals; while at the same time the wounded part is covered with a cataplasm of the same herbs bruised. The good effects are said to be speedy, and the recovery of the patient complete and certain.

<i>Mercurialis</i> (M. <i>annua</i> , Lin.)	French mercury.	The leaves.	Emollient and laxative.	A syrup.
<i>Meum</i> (<i>Aethusa meum</i> , Lin.)	Spiguel.	The root.	Aromatic and carminative.	
<i>Mezereon</i> (<i>Daphne mezereum</i> , Lin.)	Mezereon, or spurge olive.	The bark of the root.	Violently cathartic.	Decoction and powder.
<i>Millefolium</i> (<i>Achillea millefol.</i> Lin.)	Millefoil, or yarrow.	The leaves and flowers.	Mildly astringent and aromatic.	An essential oil.
<i>Millepedæ</i> (<i>Oniscus asellus</i> , Lin.)	Wood-lice, hog-lice, or flaters.		Diuretic.	The insects dried and powdered; an infusion in wine; also an ingredient in some other official preparations.
Minium. See <i>Plumbum</i> , <i>infra</i> .				
<i>Morus diabolus</i> (<i>Scabiosa succisa</i> , Lin.)	Devil's bit.	The leaves and roots.	Diaphoretic.	
<i>Morus nigra</i> (Lin.)	The mulberry-tree.	The fruit and bark of the roots.	Refrigerant, astringent, and antihelminthic.	A syrup from the juice of the fruit.
<i>Moschus</i> (M. <i>moschiferus</i> , Lin.)	Musk.		Diaphoretic and antispasmodic.	A julep.
Myristica. See <i>Nux moschata</i> , <i>infra</i> .				
<i>Myrobalani</i> (<i>Prunus myrobalanus</i> , Lin.)	Myrobalans.	The fruit.	Purgative.	
Myrrha. See <i>Gum myrrha</i> , <i>supra</i> .				
<i>Myrrhia</i> (<i>Sison Canadense</i> , Lin.)	Sweet cicely.	The leaves and seeds.	Diuretic.	
<i>Myrtillus</i> (<i>Vaccinium myrtill.</i> Lin.)	Whortle-berry.	The leaves and berries.	Astringent.	
<i>Myrtus</i> (M. <i>communis</i> , Lin.)	The myrtle.	The berries.	Astringent.	
<i>Napus</i> (<i>Brassica napus</i> , Lin.)	Sweet navew, or navew gentile.	The seeds.	Aromatic.	An ingredient in the theriaca.
<i>Nardus Indica</i> , (<i>Andropogon nardus</i> , Lin.)	Indian nard.	The roots.	Stomachic and carminative.	Ingredient in the mithridate and theriaca.
<i>Nasturtium aquaticum</i> (<i>Sisymbrium nasturtium</i> , Lin.)	Water cresses.	The leaves and juice.	Aperient and antiscorbutic.	An ingredient in the succi scorbutici.
<i>Nasturtium hortense</i> (<i>Lepidium sativum</i> , Lin.)	Garden cresses.	The leaves and seeds.	Aperient and antiscorbutic, but much weaker than the former.	
<i>Nepeta</i> (N. <i>cataria</i> , Lin.)	Nep, or catmint.	The leaves.	Aromatic and cordial.	
<i>Nephriticum lig-num</i> (<i>Gulandina moringa</i> , Lin.)	Nephritic wood.	The wood in substance.	Diuretic, but uncertain.	
<i>Nicotiana</i> (<i>Nicotiana tabacum</i> , Lin.)	Tobacco.	The leaves.	Violently emetic, cathartic, and narcotic.	An extract recommended by Stahl and other German physicians.

Nigella

List of Simples.	TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.	List of Simples.
	<i>Nigella</i> (<i>Nigella</i> <i>fativa</i> , Lin.)	Fennel-flower.	The seeds.	Aperient and diuretic, but uncertain.		
	Nitrum.	Nitre or salt-petre.		Diaphoretic, diuretic, and refrigerant.	An acid spirit and fixed alkaline salt, an aqueous decoction or solution, troches. An ingredient in many other official preparations.	
	Nummularia (<i>Ly-</i> <i>simachia nummu-</i> <i>laria</i> , Lin.)	Moneywort, or herb twopence.	The leaves.	Antiscorbutic.		
	Nux moschata (<i>Myrsifica</i> <i>arom-</i> <i>atica</i> , Lin. <i>My-</i> <i>rsifica moschata</i> , A&S. Holm.)	The nutmeg-tree.	The fruit, and co- vering called <i>mace</i> .	An excellent aromatic, cordial, and stomachic.	An expressed oil, falsely called <i>oil of mace</i> ; an essential oil; a simple water; a spirituous water; an ingredient in many official compositions.	
	Nux pistachia (<i>Pi-</i> <i>stachia vera</i> , Lin.)	The pistachia-tree.	The fruit.	Emollient and analeptic.		
	Nux vomica (<i>Styracnas nux</i> <i>vom.</i> Lin.)	Nux vomica.	The fruit.	Narcotic.		
	Nymphaea alba (Lin.)	White water-lily.	The roots and flowers.	Astringent and corroborative.		
	Ochra	Yellow ochre.		Astringent, but very weak.		
	Oenanthe (<i>Oe. cro-</i> <i>cata</i> , Lin.)	Hemlock drop- wort.	Leaves and root.	A virulent poison:	But the juice of the root, or the infusion of the leaf, has been recommended in chronic eruptions. The latter has been also found useful as an emmenagogue.	
	Olibanum. See <i>Gum</i> <i>olibanum</i> , supra.					
	Oliva (<i>Olea Euro-</i> <i>pea</i> , Lin.)	The olive-tree.	The fruit.	Emollient.	An expressed oil used in almost all ointments, plasters, &c.	
	Ononis (<i>O. spinosa</i> , Lin.)	Rest-harrow, cam- mock, or petty- whin.	The root.	Aperient and diuretic.		
	Opium (<i>Papaver</i> <i>Orientalis</i> , Lin.)	The Asiatic poppy.	The inspissated juice.	A most excellent anodyne and cordial when properly applied, but a very fatal poison if taken in too great quantity.	Purified by straining, called the <i>Thebaic extract</i> ; a sinous and spirituous tincture, called <i>liquid laudanum</i> . Also a capital ingredient in many official preparations.]	
	Opopanax. See <i>Gum</i> <i>opopanax</i> , supra.					
	Origanum (<i>O. vulg.</i> Lin.)	Wild marjoram.	The leaves.	Aromatic.	An essential oil.	
	Oryza (<i>O. sativa</i> , Lin.)	Rice.	The grain.	Emollient and refrigerant.		
	Oxylapathum (<i>Rumex acutus</i> , Lin.)	Sharp-pointed dock.	The roots and leaves.	Alterant and laxative.		
	Paeonia (<i>P. officina-</i> <i>lis</i> , Lin.)	Male and female peony.	The roots, flowers, and seeds.	Emollient and antispasmodic.	Ingredients in some anti-epileptic powders.	
	Palma (<i>Cocos buty-</i> <i>racea</i> , Lin.)	The palm-tree.	The kernels of the fruit.	Emollient and anodyne.	An expressed oil used in stomachic plasters.	
	Palma Christi. See <i>Ricinus</i> , infra.					

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Papaver album (<i>P. somniferum</i> , Lin.)	The white poppy.	The heads.	Anodyne.	A syrup.
Papaver erraticum (<i>P. rhæas</i> , Lin.)	Red poppy, or corn-rose.	The flowers.	Valued chiefly for the colour they communicate.	A syrup.
Paralyfis (<i>Primula veris offic.</i> Lin.)	Cowslip.	The flowers.	Corroborant and antispasmodic.	A syrup.
Parcira brava (<i>Cis- sampelos parcira</i> , Lin.)	Parcira brava.	The root.	Attenuant, diuretic, and lithon- triptic.	
Parietaria (<i>P. of- ficinalis</i> , Lin.)	Pellitory of the wall.	The leaves.	Emollient and di- uretic.	Ingredient in a nephritic de- coction.
Pastinaca (<i>P. sati- va</i> , Lin.)	Garden parsnip.	The roots and seeds.	Emollient and aro- matic.	
Pastinaca silvestris (Lin.)	Wild parsnip.	The seeds.	Aromatic.	
Pentaphyllum (<i>Potentilla rep- tans</i> , Lin.)	Cinquefoil.	The root.	Astringent.	
Perficaria urens (<i>Polygonum hy- dropiper</i> , Lin.)	Bitter arsmart, lake-weed, or water-pepper.	The leaves.	Diuretic and deter- gent when exter- nally applied.	
Perficaria mitis (<i>Polygonum per- fic.</i> Lin.)	Spotted arsmart.	The leaves.	Antiseptic and a- stringent.	
Perfica (<i>Amygdalus perfica</i> , Lin.)	The peach-tree.	The leaves, flowers, and fruit.	Laxative, anthel- mintic, and re- frigerant.	
Peruvianus cortex (<i>Cinchona offic- nalis</i> , Lin.)	The quinquina, or Jesuit's-bark- tree.	The bark.	A most excellent corroborative.	An extract, a resin, a spirituous tincture, a compound tin- cture, a tincture in volatile spirit; also an ingredient in the stomachic tincture.
Petasites (<i>Tussilago petasites</i> , Lin.)	Butterbur.	The root.	Aromatic, aper- ient, and deob- scurant.	
Petroleum.	Rock oil.		Anodyne and cor- roborative when applied external- ly.	
Petroleum Barba- denſe (<i>Bitumen petroleum</i> , Lin.)	Barbadoes tar.		Discutient, sudori- fic, and corrobo- rative.	
Petroelinum (<i>A- gium petroelinum</i> , Lin.)	Common parsley.	The roots, leaves, and seeds.	Aperient and some- what aromatic.	The seeds an ingredient in an electuary.
Peucedanum (<i>P. of- ficinale</i> , Lin.)	Hog's-fennel, or sulphur-wort.	The root.	Aperient, stimu- lating, and er- rhine.	
Pimenta (<i>Myrtus pimenta</i> , Lin.)	Pimento, Jamaica pepper, or all- spice.	The berry.	Aromatic and sti- mulant.	The basis of a distilled wa- ter, a spirit, and an essen- tial oil.
Pimpinella sangui- forba (<i>Sanguifor- ba officinalis</i> , Lin.)	The greater wild burnet.	The leaves.	Astringent.	
Pimpinella faxifra- ga (Lin.)	Burnet faxifrage.	The root, leaves, and seeds.	Diaphoretic, diu- retic, and anti- scorbutic.	
Pinus sylvestris (Lin.)	The pine-tree.	The kernels of its fruit or cones, and resin.	The kernels emol- lient; for the re- sin, see <i>Terebin- thina</i> , infra.

					eye.

TECHNICAL NAMES. ENGLISH NAMES.		PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Pyrethrum (<i>Anthemis pyrethra</i> , Lin.)	Pellitory of Spain.	The root.	Promotes the salival flux.	
Quassia (<i>Q. Simarouba</i> , Lin.)	Simarouba.	The bark.	Antifeptic; useful in dysentery.	See <i>Ed. Phil. Trans.</i> vol. ii.
Quassia (<i>Q. amara</i> , Lin.)	Quassy.	The wood.	Stomachic and tonic.	An extract.
Quercus (<i>Q. robur</i> , Lin.)	Oak-tree.	The bark.	Strongly astringent.	
Quercus marina (<i>Fucus vesiculosus</i> , Lin.)	Sea-wrack or Sea-oak.	The herb.	Astringent and detergent.	A powder of the burnt herb.
Radix Indica Lopeziana (<i>Gamb. Advers.</i>)	Indian or Lopez root.		Astringent.	
Raphanus ruscitarnus (<i>Cochlearia armoracea</i> , Lin.)	Horfe-radish.	The root.	Stimulating and attenuant.	A compound water.
Rhabarbarum (<i>Rheum palmat.</i> Lin.)	Rhubarb.	The root.	Cathartic and stomachic.	Toasted; a watery infusion; vinous and spirituous tinctures; and an ingredient in several official compositions.
Rhamnus catharticus. See <i>Spina cervina</i> , infra.)				
Rhaponticum (<i>Rheum rhopon.</i> Lin.)	Rhapontic.	The roots.	Laxative.	
Rhododendron chrysanthemum (Lin.)	Rhododendron.	The herb.	Powerfully sedative.	Decoction and powder; lately found serviceable in the gout and rheumatism.
Ribes nigrum (Lin.)	The black-currant bush.	The fruit.	Refrigerant and detergent.	} A jelly.
Ribes rubrum (Lin.)	The red-currant bush.	The fruit.	Ditto.	
Ricinus, (<i>R. communis</i> , Lin.)	Palma Christi.	The seed.	Laxative, anthelmintic.	Expressed oil.
Rosa damascena (<i>R. centifolia</i> , Lin.)	Damask rose.	The flower.	Aromatic and gently laxative.	A distilled water and syrup.
Rosa rubra (<i>R. Gallica</i> , Lin.)	The red rose.	The flower.	Astringent and corroborative.	A conserve, honey, tincture, troches, vinegar, and syrup. An ingredient in several official compositions.
Rosmarinus hortensis (<i>R. officinalis</i> , Lin.)	Rosemary.	The tops and flowers.	A fine aromatic and cordial.	An essential oil; a distilled spirit called <i>Hungary water</i> . An ingredient in many cordial and antispasmodic medicines.
Rubia tinctorum, (Lin.)	Madder.	The root.	Aperient and detergent.	
Rubus idæus, (Lin.)	The rasp-berry bush.	The fruit.	Refrigerant.	A syrup.
Rubus niger (<i>R. fruticosus</i> , Lin.)	The bramble.	The leaves.	Astringent.	
Rufcus (<i>R. aculeatus</i> , Lin.)	Butcher's-broom, or knee-holly.	The root.	Aperient.	Ingredient in diet-drinks.
Ruta (<i>R. graveolens</i> , Lin.)	Broad-leaved rue.	The leaves and seeds.	Powerfully stimulating, attenuating, and detergent.	An extract; and an ingredient in several compositions.

TECHNICAL NAMES.	ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Sabadilla. See <i>Cevadilla</i> , supra.				
Sabina (<i>Juniperus sabina</i> , Lin.)	Savin.	The leaves or tops.	A stimulating aperient.	An essential oil; a watery extract; and an ingredient in several official compositions.
Saccharum (<i>Arundo saccharifera</i> , Lin.)	Sugar, refined and brown.			
Saccharum cantum, album & rubrum.	Sugar-candy, white and brown.		Emollient and laxative.	
Sagapenum (<i>Ferula orientalis</i> , Lin.)	Gum sagapenum.		Aperient and deobstruent.	An ingredient in several antispasmodic medicines.
Sal alkali vegetabile.	Vegetable alkaline salt, or pearl-salt.		Aperient, diuretic, and caustic.	The basis of a great number of neutral salts.
Sal alkali minerale.	Mineral alkali, salt of Soda, or basis of sea-salt.		Ditto.	Ditto.
Sal ammoniac. See <i>Ammoniac</i> .				
Sal catharticus amarus.	Epsom salt.		Cathartic.	Magnesia.
Sal commune.	Common salt.		In small doses stimulant, in large ones cathartic.	
Salicaria (<i>Lythrum Salicaria</i> , Lin.)	Purple loose-strife.	The herb.	Astringent.	
Salix (<i>S. fragilis</i> , Lin.)	The crack-willow.	The bark.	Corroborant.	
Salvia (<i>S. officinalis</i> , Lin.)	Common sage.	The leaves.	Moderately stimulating and astringent.	Infusions.
Sambucus (<i>S. nigra</i> , Lin.)	Common black-berryed alder.	The leaves, bark, flowers and berries.	Cathartic, aromatic, and aperient.	A rob for internal use from the berries, and an ointment and oil from the flowers and bark; the flowers are also ingredients in some compound waters.
Sanguis draconis, (<i>Calamus rotang</i> , <i>Dracena druto</i> , <i>Pterocarpus, draco</i> , &c. Lin.)	Dragon's-blood.		Astringent.	An ingredient in some official compositions.
Sanicula (<i>S. Europaea</i> , Lin.)	Sanicle.	The leaves.	Supposed to be corroborant.	
Santalum citrinum, (<i>S. album</i> , Lin.)	Yellow sanders.	The wood.	Greatly recommended by Hoffman as a restorative.	Essential oil; extract.
Santalum rubrum, (<i>Pterocarpus santalinus</i> , Lin.)	Red sanders.	The wood.	Used only for its colour.	
Santonium (<i>Artemisia santonica</i> , Lin.)	Worm-seed.		Anthelmintic.	

TECHNICAL NAMES. ENGLISH NAMES.		PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Sapo durus.	Hard Spanish soap.	}	Resolvent and stimulating.	{ The first gives name to a plaster, liniment, balsam, and pills; the second is an ingredient in the milder caustic; and the third in an anodyne plaster.
Sapo mollis.	Common soft soap.			
Sapo niger.	Black soap.			
Saponaria (<i>S. officinalis</i> , Lin.)	Soapwort or bruise-wort.	The herb and root.	Aperient, corroborant, and sudorific.	Tincture; extract.
Sarcocolla (<i>Penaea farcoc.</i> Lin.)	Gum sarcocoll.		Supposed a vulnerary.	Ingredient in the pulvis æcerussa.
Sarsaparilla (<i>Smilax farfap.</i> Lin.)	Sarsaparilla.	The root.	Alterant, and diaphoretic.	Infusions and extract.
Sassafras (<i>Laurus sassafras</i> , Lin.)	Sassafras.	The root.	Alterant, aperient, and corroborant.	An essential oil; an ingredient in some officinal preparations.
Satureia (<i>S. hortensis</i> , Lin.)	Summer savory.	The leaves.	A very pungent warm aromatic.	
Satyrium mas (<i>Orchis mascula</i> , Lin.)	Orchis.	The root.	Coagulant and corroborative.	Supposed to be a preparation from a root of this kind.
Saxifraga alba (<i>S. granulata</i> , Lin.)	White-flowered saxifrage.	The roots and leaves.	{ Supposed to be aperient, diuretic, and lithontriptic, but without just foundation.	
Saxifraga vulgaris (<i>Peucedanum fistula</i> , Lin.)	Meadow saxifrage.	The leaves and seeds.		
Scabiosa (<i>S. arvensis</i> , Lin.)	Scabious.	The leaves.	Aperient, sudorific, and expectorant.	
Scammonium (<i>Convolvulus scam.</i> Lin.)	Scammony.	Roots.	Strongly cathartic.	Gives name to a powder, and is an ingredient in some officinal preparations.
Scilla (<i>S. maritima</i> , Lin.)	The squill, or sea-onion.	The root.	Powerfully diuretic, stimulant, and expectorant.	A syrup, vinegar, oxymel, pills; the root dried, baked, and made into troches.
Scolopendrium.	See <i>Lingua cervina</i> , supra.			
Scordium (<i>Teucrium scordium</i> , Lin.)	Water germander.	The leaves.	Deobstruent, diuretic, and sudorific, but doubtful.	An ingredient in mithridate, theriaca, and several other preparations.
Scorzonera (<i>S. bifpanica</i> , Lin.)	Viper's grass.	The root.	Cordial and stimulant, but doubtful.	
Scrophularia (<i>S. nodosa</i> , Lin.)	Fig-wort.	The leaves and root.	Supposed corroborant, but doubtful.	
Sebesten (<i>Cordia myxa</i> , Lin.)	Sebesten plum.		Emollient.	
Sedum acre (Lin.)	Wall stone crop, or wall pepper.	The fresh plant.	Strongly purgative, emetic, and diuretic.	
Sedum majus (<i>S. album</i> , Lin.)	Greater houseleek.	The leaves.	Refrigerant.	
Seneca. See <i>Polygala seneca</i> , supra.				
Senna (<i>Cassia senna</i> , Lin.)	Senna.	The leaves.	Cathartic.	Infusion, spirituous tinctures, compound powders, and an electuary.

TECHNICAL NAMES. ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.
Serpentaria Virg- niana (<i>Aristolochia serpentaria</i> , Lin.)	Virginian snake- weed.	The root.	A warm diaphoretic and diuretic.
Serpyllum (<i>Thymus serpyll.</i> Lin.)	Mother of thyme.	The herb.	Aromatic.
Seclis vulgaris, (<i>Tordylium officin.</i> Lin.)	Common hartwort.	The seeds.	} Agreeable aromatics, but neglected. <i>Lewin.</i>
Seclis masiliensis (<i>Seclis elatum</i> , Lin.)	Hartwort of Mar- seilles.	The seeds.	
Sigillum Salomo- nis (<i>Convallaria polygon.</i> Lin.)	Solomon's seal.	The root.	Probably emollient.
Simarouba. See <i>Quassia simarouba</i> , supra.			
Sinapi (<i>Sinapis alba & nigra</i> , Lin.)	Mustard.	The seeds, black and white.	Strongly pungent and stimulant.
Sium (<i>S. nadiiflorum</i> , Lin.)	Creeping skerrit, or water parsnip.	The herb.	The juice serviceable in some cutaneous disorders.
Solanum (<i>S. nigr.</i> Lin.)	Nightshade.	The leaves.	Powerfully evacuant.
Spermaceti (<i>Physter macrocephalus</i> , Lin.)	Spermaceti.		A mild emollient. Gives name to a lochoch.
Spigelia (<i>S. Marilandica</i> , Lin.)	Indian pink.	The root.	Anthelmintic.
Spina cervina, (<i>Rhamnus catharticus</i> , Lin.)	Buckthorn.	The berries.	Strongly cathartic. A syrup.
Spiritus vinosi.	Vinous spirits.		Cordial and stimulant.
Spengia (<i>S. officinal.</i> Lin.)	Sponge.		Used as a tent for dilating ulcers, &c.
Stannum.	Tin.		Anthelmintic.
Staphisagria (<i>Delphinium staphisagria</i> , Lin.)	Stavesacre.	The seeds.	A violent cathartic taken internally, Its external application destroys lice and other insects.
Stoechas (<i>Lavendula stoechas</i> , Lin.)	Arabian stoechas, or French lavender.	The flowers.	Aromatic.
Stramonium (<i>Datura stramon.</i> Lin.)	Thorn-apple.	The herb.	Narcotic.
Styrax calamita (<i>S. Styracis</i> , Lin.)	Liquid storax.		Aromatic, stimulant, and nervine.
Styrax liquida (<i>Liquidambar styraciflua</i> , Lin.)	Liquid storax.		
Suber (<i>Quercus sub.</i> Lin.)	The cork-tree.	The bark.	Astringent.

List of Simples.	TECHNICAL NAMES. ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.	List of Simples.
	Succinum. Amber.		Astringent and cor- roborant.	A tincture, balsam, essential oil, and an ingredient in se- veral official preparations.	
	Sulphur. Sulphur, and flow- ers of sulphur.		Laxative, diapho- retic, and alte- rant.	Solutions in different kinds of oils called <i>balsams</i> , and an ingredient in some oint- ments.	
	Sumach (<i>Rhus co- riaria</i> , Lin.)	The leaves and seeds.	Astringent.		
	Tacamahac (<i>Popu- lus balsamifera</i> , Lin.)	The resin.	Discutient, emolli- ent, and suppu- rative.	An ingredient in several pla- sters.	
	Tamarindus (<i>T. Indica</i> , Lin.)	The fruit.	Refrigerant and laxative.	Ingredients in some laxative electuaries.	
	Tamariscus (<i>Ta- marix Gallica</i> , Lin.)	The tamarisk-tree. The leaves and bark.	Astringent.		
	Tanacetum (<i>T. vulgare</i> , Lin.)	Tansy. The leaves, flowers, and seeds.	Stimulating, anti- spasmodic, and anthelmintic.		
	Taraxacum (<i>Leon- odon tarax.</i> Lin.)	The leaves and root.	Attenuating and resolvent.	A distilled spirit, recom- mended by professor De- lius of England in asthma- tic and hydropic affec- tions.	
	Tartarum. Tartar.		Refrigerant and ca- thartic.	Purified from its earthy parts, and called <i>cream of tartar</i> , the basis of some useful pur- ging salts. An alkali is al- so prepared from it by fire.	
	Terebinthina ^a Ve- neta (<i>Pinus larix</i> , Lin.)	Venice turpentine.	} Warm stimula- ting diuretics and aperients.		
	Terebinthina Ar- gentoratensis.	Straßburgh turpen- tine.			
	Terebinthina Chia.	Chian, or Cyprus turpentine.			
	Terebinthina com- munis.	Common turpen- tine.	Used chiefly in ex- ternal applica- tions.	An essential oil. The resi- duum forms the <i>resina alba</i> <i>et nigra</i> , or white and black rosin of the shops, used in almost every ointment.	
	Terra Japonica. See <i>Catechu</i> , supra.				
	Thapsus barbatus (<i>Verapicum thap- sus</i> , Lin.)	Great white mul- lein.	The leaves and flowers.	Analeptic.	A spirituous extract from the flowers.
	Thea bohea et vi- ridis (Lin.)	Bohea and green tea.	The leaves.	Cordial, diuretic, and diaphoretic.	An infusion.
	Thlaspi (<i>T. ar- vense</i> , Lin.)	Treacle, or mithri- date mustard.	The seeds.	Aromatic and sti- mulant.	Ingredient in theriaca.
	Thus vulgare.	Common frank- incense.		Supposed corrobo- rative.	Ingredient in some warm pla- sters.
	Thymus citratus.	Lemon thyme.	The leaves.	An agreeable aro- matic.	A distilled water and essential oil.
	Thymus vulgaris.	Common thyme.	The leaves.	An agreeable aro- matic.	A distilled water and essential oil.
	Tilia (<i>T. Europaea</i> , Lin.)	The lime or linden tree.	The flowers.	Antispasmodic.	Infusion.
	Tithymalus (<i>Eup- horbia lathyris</i> , Lin.)	The spurge.	The juice of the root.	Violently cathartic.	

List of Simplex.	TECHNICAL NAMES. ENGLISH NAMES.	PARTS USED IN MEDICINE.	VIRTUES.	PREPARATIONS FROM THEM.	List of Simplex.
	Tormentilla (<i>T. erecta</i> , Lin.)	Tormentil, or sept-foil.	The root.	Astringent.	An ingredient in several official compositions.
	Trichomanes (<i>Asplenium trich.</i> , Lin.)	Maidenhair.	The herb.	Pectoral.	Decoction and syrup.
	Trifolium paludo- sum (<i>Menyanthes trifoliata</i> , Lin.)	Marsh trefoil, or buck bean.	The leaves.	Laxative and alterant.	
	Triticum (<i>T. hybernum</i> , Lin.)	Wheat.	The grain and flour.	Nutritive and glutinous.	Starch.
	Turpethum (<i>Convolvulus turpethum</i> , Lin.)	Turbith.	The root.	Violently cathartic.	An extract.
	Tussilago (<i>T. farfara</i> , Lin.)	Coltsfoot.	The leaves and flowers.	Emollient and mucilaginous.	An ingredient in pectoral decoctions.
	Tutia.	Tutty.		Ophthalmic.	Ingredient in several ointments, and collyria.
	Valeriana fylvestris (<i>Val. officinalis</i> , Lin.)	Wild valerian.	The root.	Antispasmodic.	A tincture in proof spirit, and in volatile spirit; also an ingredient in several cephalic and anti-epileptic medicines.
	Veratrum. See <i>Helleborus albus</i> , supra.				
	Verbalcum. See <i>Thapsus</i> , supra.				
	Veronica mas (<i>V. officinalis</i> , Lin.)	Male speedwell.	The leaves.	Aperient and pectoral.	Infusions.
	Vinum.	Wine.		Cordial and corroborant.	A menstruum for a great number of medicinal substances.
	Viola (<i>V. odorata</i> , Lin.)	The single violet.	The flowers.	Laxative.	A syrup.
	Vipera (<i>Coleuber berus</i> , Lin.)	The viper.	The flesh and fat.	Restorative and emollient.	A vinous tincture; an ingredient in theriaca.
	Vitis vinifera, (<i>Lin.</i>)	The vine.	The leaves, sap, flowers, and fruit.	Astringent, diuretic, aromatic, and pectoral.	Wine. The dried fruit or raisins are ingredients in some pectoral and stomachic medicines.
	Ulmus (<i>U. campestris</i> , Lin.)	The elm-tree.	The inner bark.	Astringent.	A decoction recommended by Dr Lettison in obstinate cutaneous eruptions.
	Winteranus cortex (<i>Winters aromatica</i> , Lin.)	Winter's bark.		Aromatic.	
	Urtica (<i>U. dioica</i> , Lin.)	The nettle.	The herb.	Rubefacient.	
	Uva ursi (<i>Arbutus uva ursi</i> , Lin.)	Whortle-berry.	The leaves.	Astringent and lithontriptic.	
	Zedoaria (<i>Kämpferia rotunda</i> , Lin.)	Zedoary.	The root.	Stomachic and corroborant.	An extract with proof spirit.
	Zincum.	Zinc.		Supposed to be a good antiepileptic.	The metal reduced to a calx by fire. Calamine and tutty are a kind of ores of this metal. These last are the basis of two official ointments. A salt produced by its combination with the vitriolic acid. See CHEMISTRY-Index.
	Zinziber (<i>Amomum sinzib.</i> Lin.)	Ginger.	The root.	Aromatic.	A syrup. Also an ingredient in several official compositions.

General
Titles.

General Titles including several SIMPLS.

- The five opening roots : { Smallage,
A sparagus,
Fennel,
Parley,
Butchers broom,
- The five emollient herbs : { Marshmallows,
Mallows,
Mercury,
Pellitory of the wall,
Violets.
- The four cordial flowers : { Borage,
Bugloss,
Roses,
Violets.
- The four greater hot seeds : { Anise,
Caraway,
Cummin,
Fennel.
- The four lesser hot seeds : { Bishopfeed,
Stone parley,
Smallage,
Wild carrot.
- The four greater cold seeds : { Water melons,
Cucumbers,
Gourds,
Melons.
- The four lesser cold seeds : { Succory,
Endive,
Lettuce,
Purslane.
- The four capillary herbs : { Maidenhair,
English maindenhair,
Wall rue,
Ceterach.
- The four carminative flowers : { Camomile,
Feverfew,
Dill,
Melilot.

The simples of each of the above classes have been often employed together under the respective general appellations. This practice has entirely ceased amongst us ; and accordingly these denominations are now expunged both from the London and Edinburgh pharmacopœias, and they are now retained in very few of the foreign ones. But as these articles are frequently mentioned under their general titles by writers of eminence, it was imagined that the above enumeration of them might be of some use.

GENERAL RULES for the Collection and Preservation of SIMPLS.

Roots.

Annual roots are to be taken up before they shoot
Nº 197.

out stalks or flowers : Biennial ones, chiefly in the autumn of the same year in which the seeds were sown : The perennial, when the leaves fall off, and therefore generally in the autumn. Being washed clean from dirt, and freed from the rotten and decayed fibres, they are to be hung up in a warm, shady, airy place, till sufficiently dried. The thicker roots require to be slit longitudinally, or cut transversely into thin slices. Such roots as lose their virtues by exsiccation, or are desired to be preserved in a fresh state, for the greater convenience of their use in certain forms, are to be kept buried in dry sand.

There are two seasons in which the biennial and perennial roots are reckoned the most vigorous, the autumn and spring ; or rather the time when the stalks or leaves have fallen off, and that in which the vegetation is just to begin again, or soon after it has begun ; which times are found to differ considerably in different plants.

The college of Edinburgh, in the two first editions of their pharmacopœia, directed them to be dug in the spring, after the leaves were formed ; in the third edition the autumn was preferred. The generality of roots appear, indeed, to be most efficacious in the spring : but as at this time they are also the most juicy, and consequently shrivel much in drying, and are rather more difficultly preserved, it is commonly thought most advisable to take them up in autumn. No rule, however, can be given, that shall obtain universally ; arum root is taken even in the middle of summer, without suspicion of its being less active than at other seasons ; while angelica root is inert during the summer, in comparison of what it was in the autumn, spring, or winter.

HERBS AND LEAVES.

Herbs are to be gathered when the leaves have come to their full growth, before the flowers unfold ; but of some plants the flowery tops are preferred. They are to be dried in the same manner as roots.

For the gathering of leaves, there cannot perhaps be any universal rule any more than for roots ; for though most herbs appear to be in their greatest vigour about the time of their flowering, or a little before, there are some in which the medicinal parts are more abundant at an earlier period.

Thus mallow and marshmallow leaves are most mucilaginous when young, and by the time of flowering approach more to a woody nature. A difference of the same kind is more remarkable in the leaves of certain trees and shrubs : the young buds, or rudiments of the leaves, of the black poplar tree, have a strong fragrant smell, approaching to that of storax ; but by the time that the leaves have come to their full growth, their fragrance is exhausted.

Herbs are directed by most of the pharmaceutical writers to be dried in the shade ; a rule which appears to be very just, though it has sometimes been misunderstood. They are not to be excluded from the sun's heat, but from the strong action of the solar light ; by which last their colours are more liable to be altered or destroyed than those of roots. Slow drying of them in a cool place is far from being of any advantage : both their colours and virtues are preserved in greatest perfection.

Collection,
&c. of
Samples.

Collection,
&c. of
Samples.

perfection when they are dried hastily by the heat of common fire as great as that which the sun can impart: the juicy ones, in particular, require to be dried by heat, being otherwise subject to turn black. Odoriferous herbs, dried by fire till they become friable, discover indeed, in this arid state, very little smell; not that the odorous matter is dissipated, but on account of its not being communicated from the perfectly dry subject to dry air; for as soon as a watery vehicle is supplied, whether by infusing the plant in water, or by exposing it for a little time to a moist air, the odorous parts begin to be extracted by virtue of the aqueous moisture, and discover themselves in their full force.

Of the use of heat in the drying of plants, we have an instance in the treatment of tea among the Chinese. According to the accounts of travellers, the leaves, as soon as gathered, are brought into an apartment furnished with a number of little furnaces or stoves, each of which is covered with a clean smooth iron plate; the leaves are spread on the plates, and kept rolling with the hands till they begin to curl up about the edges; they are then immediately swept off on tables, on which one person continues to roll them, while another fans them that they may cool hastily: this process is repeated two or three times, or oftener, according as the leaves are disposed to unbend on standing.

EXSICCATION OF HERBS AND FLOWERS.

Herbs and flowers are to be dried by the gentle heat of a stove or common fire, and only in that quantity at a time by which the exsiccation may be very soon finished. By this means their strength is best preserved; and this is indicated in proportion as they retain their native colour.

But the leaves of hemlock, and some other herbs replete with a subtle volatile matter, are to be powdered immediately after the exsiccation, and preserved in glass vessels, well shut.

FLOWERS.

Flowers are to be gathered when moderately expanded, on a clear dry day, before noon. Red roses are taken before they open, and the white heels clipped off and thrown away.

The quick drying, above recommended for the leaves of plants, is more particularly proper for flowers; in most of which both the colour and smell are more perishable than in leaves, and more subject to be impaired by slow exsiccation. Of the flowers which come fresh into the apothecaries hands, the only ones employed dry in the London pharmacopœia are red roses; and these, in all the compositions in which they are used in a dry state, are expressly ordered to be dried hastily. One of the most valuable aromatics of European growth, saffron, is part of a flower, dried on paper on a kind of kiln, with a heat sufficient to make it sweat, taking care only not to endanger the scorching of it.

It may here be observed, that the virtues of flowers are confined to different parts of the flower in different plants. Saffron is a singular production growing at the end of the style or pistil. The active part of

momile flowers is the yellow disk, or button in the middle: that of lilies, roses, clove-july-flowers, violets, and many others, the petala or flower-leaves; while rosemary has little virtue in any of these parts, the fragrance admired in the flowers of this plant residing chiefly in the cups.

SEEDS AND FRUITS.

Seeds should be collected when ripe, and beginning to grow dry, before they fall off spontaneously. Fruits are also to be gathered when ripe, unless otherwise ordered.

Of the fruits whose collection comes under the notice of the apothecary, there are few which are used in an unripe state; the principal is the sloe, whose virtue as a mild astringent is much diminished by maturation. The fruit of the orange tree, raised in our gardens or green-houses, is sometimes gathered in a state of much greater immaturity, soon after it is formed on the tree, before it has acquired its acid juice; at this time it proves an elegant aromatic bitter, nearly resembling what are called *Currassoe oranges*, which appear to be no other than the same fruit gathered at the same period in a warmer climate.

The rule for collecting seeds is more general than any of the others, all the official seeds being in their greatest perfection at the time of their maturity. As seeds contain little watery moisture, they require no other warmth for drying them than that of the temperate air in autumn: such as abound with a gross expressible oil, as those commonly called the *cold seeds*, should never be exposed to any considerable heat; for this would hasten the rancidity, which, however carefully kept, they are very liable to contract. Seeds are best preserved in their natural husks or coverings, which should be separated only at the time of using; the husk, or cortical part, serving to defend the seed from being injured by the air.

WOODS AND BARKS.

The most proper season for the felling of woods, or shaving off their barks, is generally the winter.

No woods of our own growth are now retained by the London or Edinburgh colleges. The only two which had formerly a place in the catalogues of simples were the juniper and the box; the first of which is never kept in the shops, or employed in practice; the other may be procured from the turner; and it is indifferent at what season it has been cut down, being at all times sufficiently fit for the only use to which it was applied, the yielding an empyreumatic oil by distillation in a strong fire.

It may be doubted, whether barks are not generally more replete with medicinal matter in summer and spring than in winter. The barks of many trees are in summer so much loaded with resin and gum as to burst spontaneously, and discharge the redundant quantity. It is said that the bark of the oak answers best for the tanners at the time of the rising of the sap in spring: and as its use in tanning depends on the same astringent quality for which it is used in medicine, it should seem to be also fittest for medicinal purposes in the spring. It may be observed likewise, that it is in

Collection, this last season that barks in general are most convenient
 &c. of peeled off.
 Simples.

ANIMAL SUBSTANCES.

Animal substances are to be chosen in their

most perfect state, unless they be ordered otherwise.
 Collection
 &c. of
 Simples.

Whatever virtues these bodies may have, they are supposed to be best when they have attained to their common full growth.

M A T

Material
 ||
 Mathematics.

MATERIAL, denotes something composed of matter. In which sense the word stands opposed to immaterial. See MATTER and METAPHYSICS.

MATERIALISTS, a sect in the ancient church, composed of persons who, being prepossessed with that maxim in the ancient philosophy, *Ex nihilo nihil fit*, "Out of nothing nothing can arise," had recourse to an internal matter, on which they supposed God wrought in the creation; instead of admitting God alone as the sole cause of the existence of all things. Tertullian vigorously opposes the doctrine of the materialists in his treatise against Hermogenes, who was one of their number.

Materialists is also a name given to those who maintain that the soul of man is material; or that the principle of perception and thought is not a substance distinct from the body, but the result of corporeal organization: See METAPHYSICS. There are others, called by this name, who have maintained that there is nothing but matter in the universe; and that the Deity himself is material. See SPINOZISM.

MATHAM (Jaques), an engraver of considerable eminence, was born at Haerlem in 1571, and after the death of his father, Henry Goltzius, a celebrated painter and engraver, married his mother. From his father-in-law he learned the art of engraving. He went to Italy, to complete his studies from the works of the greatest masters; and in that country he engraved a considerable number of plates. At his return, he worked under the eye of Goltzius, and produced many very valuable prints. Following the example of his father-in-law, he worked entirely with the graver, in a clear, free style; and though he never equalled him in point of taste or correctness of drawing, especially when confined to the naked parts of the human figure, most of his prints are greatly esteemed.

MATHEMATICS, the science of quantity; or a science that considers magnitudes either as computable or measurable.

The word in its original, μαθηματις, signifies discipline, or science in the general; and seems to have been applied to the doctrine of quantity, either by way of eminence, or because, this having the start of all other sciences, the rest took their common name therefrom. See SCIENCE.

For the origin of the mathematics, Josephus dates it before the flood, and makes the sons of Seth observers of the course and order of the heavenly bodies: he adds, that, to perpetuate their discoveries, and secure them from the injuries either of a deluge or a conflagration, they had them engraven on two pillars, the one of stone, the other of brick; the former of which he says was standing in Syria in his days. See ASTRONOMY.

The first who cultivated mathematics after the flood

M A T

Mathematics.

were the Assyrians and Chaldeans; from whom, the same Josephus adds, they were carried by Abraham to the Egyptians; who proved such notable proficient, that Aristotle makes no scruple to fix the first rise of mathematics among them. From Egypt, 584 years before Christ, they passed into Greece through the hands of Thales; who having learned geometry of the Egyptian priests, taught it in his own country. After Thales, comes Pythagoras; who, among other mathematical arts, paid a particular regard to arithmetic; fetching the greatest part of his philosophy from numbers: he was the first, as Lactius tells us, who abstracted geometry from matter; and to him we owe the doctrine of incommensurable magnitude, and the five regular bodies, besides the first principles of music and astronomy. Pythagoras was seconded by Anaxagoras, Cænopides, Bristo, Antipho, and Hippocrates of Scio; who all applied themselves particularly to the quadrature of the circle, the duplicature of the cube, &c. but the last with most success: this last is also mentioned by Proclus, as the first who compiled elements of mathematics.

Democritus excelled in mathematics as well as physics; though none of his works in either kind are extant, the destruction of which some authors lay at Aristotle's door. The next in order is Plato, who not only improved geometry, but introduced it into physics, and so laid the foundation of a solid philosophy. Out of his school proceeded a crowd of mathematicians. Proclus mentions 13 of note; among whom was Leodamus, who improved the analysis first invented by Plato; Theætetus, who wrote elements; and Archimedes, who has the credit of being the first who applied mathematics to use in life. These were succeeded by Neocles and Theon, the last of whom contributed to the elements. Eudoxus excelled in arithmetic and geometry, and was the first founder of a system of astronomy. Menechmus invented the conic sections, and Theudius and Hermotimus improved the elements.

For Aristotle, his works are so stored with mathematics, that Blancanus compiled a whole book of them: out of his school came Eudemus and Theophrastus; the first of whom wrote of numbers, geometry, and invisible lines; the latter, a mathematical history. To Aristotle, Idorus, and Hypicles, we owe the books of solids; which, with the other books of elements, were improved, collected, and methodised by Euclid, who died 284 years before Christ.

An hundred years after Euclid, came Eratosthenes and Archimedes. Cotemporary with the latter was Conon, a geometrician and astronomer. Soon after came Apollonius Pergæus; whose conics are still extant. To him are likewise ascribed the 14th and 15th books of Euclid, which are said to have been contracted

ted by Hippicles. Hipparchus and Menelaus wrote on the spherics in a circle, the latter also on spherical triangles: Theodosius's three books of spherics are still extant. And all these, Menelaus excepted, lived before Christ.

A. D. 70. Ptolemy of Alexandria was born; the prince of astronomers, and no mean geometrician: he was succeeded by the philosopher Plutarch, of whom we have still extant some mathematical problems. After him came Eutocius, who commented on Archimedes, and occasionally mentions the inventions of Philo, Diocles, Nicomedes, Sporus, and Heron, on the duplicature of the cube. To Ctesibius of Alexandria we owe our pumps; and Geminus, who came soon after, is preferred by Proclus to Euclid himself.

Diophantus of Alexandria was a great master of numbers, and the first inventor of algebra: among others of the ancients, Nicomachus is celebrated for his arithmetical, geometrical, and musical works; Serenus, for his books on the sections of the cylinder; Proclus, for his comments on Euclid; and Theon has the credit, among some, of being author of the books of elements ascribed to Euclid. The last to be named among the ancients, is Pappus of Alexandria, who flourished A. D. 400, and is celebrated for his books of mathematical collections still extant.

Mathematics are commonly distinguished into *pure and speculative*, which consider quantity abstractedly; and *mixed*, which treat of magnitude as subsisting in material bodies, and consequently are interwoven every where with physical considerations.

Mixed mathematics are very comprehensive; since to them may be referred astronomy, optics, geography, hydrostatics, mechanics, fortification, navigation, &c. See the articles ASTRONOMY, OPTICS, &c.

Pure mathematics have one peculiar advantage, that they occasion no disputes among wrangling disputants, as in other branches of knowledge; and the reason is, because the definitions of the terms are premised, and every body that reads a proposition has the same idea of every part of it. Hence it is easy to put an end to all mathematical controversies, by showing, either that our adversary has not stuck to his definitions, or has not laid down true premises, or else that he has drawn false conclusions from true principles; and in case we are able to do neither of these, we must acknowledge the truth of what he has proved.

It is true, that in mixed mathematics, where we reason mathematically upon physical subjects, we cannot give such just definitions as the geometricians: we must therefore rest content with descriptions; and they will be of the same use as definitions, provided we are consistent with ourselves, and always mean the same thing by those terms we have once explained.

Dr Barrow gives a most elegant description of the excellence and usefulness of mathematical knowledge, in his inaugural oration, upon being appointed professor of mathematics at Cambridge.

The mathematicians, he observes, effectually exercise, not vainly delude, nor vexatiously torment, studious minds with obscure subtilties; but plainly demonstrate every thing within their reach, draw certain conclusions, instruct by profitable rules, and unfold pleasant questions. These disciplines likewise enure and corro-

borate the mind to a constant diligence in study; they wholly deliver us from a credulous simplicity, most strongly fortify us against the vanity of scepticism, effectually restrain us from a rash presumption, most easily incline us to a due assent, and perfectly subject us to the government of right reason. While the mind is abstracted and elevated from sensible matter, daintily views pure forms, conceives the beauty of ideas, and investigates the harmony of proportions; the manners themselves are sensibly corrected and improved, the affections composed and rectified, the fancy calmed and settled, and the understanding raised and excited to more divine contemplations.

MATHEMATICAL, any thing belonging to the science of mathematics.

MATHEMATICAL Instruments, such instruments as are usually employed by mathematicians, as compasses, scales, quadrants, &c.

Machine for dividing MATHEMATICAL Instruments. See RAMSDEN'S Machine.

MATHER (Dr Cotton), an eminent American divine, born at Boston in New England in the year 1663. He was educated in Harvard college, and in 1684 became minister of Boston; in the diligent discharge of which office he spent his life, and promoted several excellent societies for the public good: particularly one for suppressing disorders, one for reforming manners, and a society of peace-makers, whose professed business it was to compose differences and prevent law-suits. His reputation was not confined to his own country: for in 1710, the university of Glasgow sent him a diploma for the degree of doctor in divinity; and, in 1714, the Royal Society of London chose him one of their fellows. He died in 1728; and is said to have published in his lifetime 382 pieces, including single sermons, essays, &c. yet several were of a larger size, among which was *Magna Christi Americana*, or an Ecclesiastical History of New-England, from its first planting in 1620 to 1698, folio. But the most remarkable of all his works was that in which, like Glanville, he defended the doctrine of witchcraft. We shall content ourselves with giving the title at large, which is as follows: "The wonders of the invisible world; being an account of the trials of several witches lately executed in New-England, and of several remarkable curiosities therein occurring. Together with, 1. Observations on the nature, the number, and the operations of the devils. 2. A short narrative of a late outrage committed by a knot of witches in Swedenland; very much resembling, and so far explaining that under which New-England has laboured. 3. Some counsels directing a due improvement of the terrible things lately done by the unusual and amazing range of evil spirits in New-England. 4. A brief discourse upon the temptations which are the more ordinary devices of Satan. By Cotton Mather; published by the special command of his excellency the governor of the province of Massachusetts's Bay in New-England." Printed first at Boston in New-England, and reprinted at London, in 1736, 4to.

MATLOCK, a town or village of Derbyshire, near Wickford, situated on the very edge of the Derwent; noted for its bath, the water of which is milk-warm; and remarkable for the huge rocks in its environs,

Matras
||
Matrice.

virons, particularly those called the *Torr*, on the east side of the Derwent, over against it, which seem to be piled one upon another. It is an extensive straggling village, built in a very romantic style, on the steep side of a mountain, rising irregularly from the bottom to nearly the summit. Near the bath are several small houses, whose situation is on the little natural horizontal parts of the mountain, a few yards above the road, and in some places the roofs of some almost touch the floors of others. There are excellent accommodations for company who resort to the bath; and the poorer inhabitants are supported by the sale of petrifications, crystals, &c. and notwithstanding the rockiness of the soil, the cliffs produce an immense number of trees, whose foliage adds greatly to the beauty of the place.

MATRASS, CUCURBIT, or BOLT-HEAD, among chemists. See CHEMISTRY, n° 579.

MATRICARIA, FEVERFEW, in botany: A genus of the polygama superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is naked; there is no pappus; the calyx hemispherical and imbricated, with the marginal leaflets solid, and something sharp. There are five species, but the only remarkable one is the parenthesis or common feverfew. This hath very fibrous clustering roots, crowned with numerous compound leaves; upright stalks branching on every side two or three feet high; garnished with compound plain leaves of seven oval folioles, cut into many parts; and all the branches terminated by many compound radiated white flowers having a yellow disk. There are varieties with double flowers, with semi-double flowers, with double fistular flowers, with a fistular disk and plain radius, with short-rayed flowers, with rayless flowers, with rayless sulphur-coloured heads, and with finely curled leaves. — All these varieties flower abundantly in June, each flower being composed of numerous hermaphrodite and female florets; the former compose the disk, the latter the radius or border, and which, in the double and fistular kinds, are very ornamental in gardens, but of a disagreeable odour; and are all succeeded by plenty of seed in autumn, by which they are easily propagated, as well as by parting the roots and cuttings.

Medical uses. This plant has received a most extraordinary character in hyssic and other affections of the nerves, as well as for being a carminative or warm stimulating bitter. Dr Lewis, however, thinks it inferior to camomile; with which he says it agrees in all its sensible qualities, only being somewhat weaker.

MATRICE, or MATRIX. See MATRIX.

MATRICE, or matrix, in dyeing, is applied to the five simple colours, whence all the rest are derived or composed. These are, the black, white, blue, red, and yellow or root colour.

MATRICE, or matrices, used by the letter-founders, are those little pieces of copper or brass, at one end whereof are engraven, dent-wise, or *en creux*, the several characters used in the composing of books. Each character, virgula, and even each point in a discourse, has its several matrix; and of consequence, its several puncheon to strike it. They are the engravers on metal that cut or grave the matrices.

Matrice
||
Matrona.

When types are to be cast, the matrice is fastened to the end of a mould, so disposed as that when the metal is poured on it, it may fall into the creux or cavity of the matrice, and take the figure and impression thereof. See *Letter-Foundery*.

MATRICES, used in coining, are pieces of steel in form of dyes, whereon are engraven the several figures, arms, characters, legends, &c. wherewith the species are to be stamped. The engraving is performed with several puncheons, which being formed in relieve, or prominent, when struck on the metal, make an indented impression, which the French call *en creux*.

MATRICULA, a register kept of the admission of officers and persons entered into any body or society whereof a list is made. Hence those who are admitted into our universities are said to be matriculated. Among ecclesiastical authors, we find mention made of two kinds of matriculæ; the one containing a list of the ecclesiastics called *matricula clericorum*; the other of the poor sublisted at the expence of the church, called *matricula pauperum*.

MATRICULA was also applied to a kind of almshouse, where the poor were provided for. It had certain revenues appropriated to it, and was usually built near the church; whence the name was also frequently given to the church itself.

MATRIMONY. See MARRIAGE.

MATRIX, in anatomy, the womb, or that part of the female of any kind, wherein the fetus is conceived and nourished till the time of its delivery. See ANATOMY, n° 108.

MATRIX is also applied to places proper for the generation of vegetables, minerals, and metals. Thus the earth is the matrix wherein seeds sprout; and marcasites are by many considered as the matrices of metals.

The matrix of ores is the earthy and stony substances in which these metallic matters are enveloped: these are very various, frequently spar, quartz, fluors, or horn-blend.

MATRON, an elderly married woman.

Jury of MATRONS. When a widow feigns herself with child in order to exclude the next heir, and a supposititious birth is suspected to be intended, then, upon the writ de *ventre inspiciendo*, a jury of women is to be impanelled to try the question whether the woman is with child or not. So, if a woman is convicted of a capital offence, and, being condemned to suffer death, pleads in stay of execution, that she is pregnant, a jury of matrons is impanelled to inquire into the truth of the allegation; and, if they find it true, the convict is respited till after her delivery.

MATRONA, (anc. geog.), a river separating Gallia Celtica from the Belgica (Cesar.) Now the Marne; which, rising in Champaign near Langres, runs north-west, and then west, and passing by Meaux falls into the Seine at Charenton, two leagues to the east of Paris.

MATRONALIA, a Roman festival instituted by Romulus, and celebrated on the kalends of March, in honour of Mars. It was kept by matrons in particular, and bachelors were entirely excluded from any share in the solemnity. The men during this feast sent presents to the women, for which a return was made.

Matroses
||
Matter.

made by them at the Saturnalia: And the women gave the same indulgence to their servants; now which the men gave to theirs at the feast of Saturn, serving them at table, and treating them as superiors.

MATROSSES, are soldiers in the train of artillery, who are next to the gunners, and assist them in loading, firing, and sponging the great guns. They carry firelocks, and march along with the store-waggons, both as a guard, and to give their assistance in case a waggon should break down.

MATSYS (Quintin), painter of history and portraits, was born at Antwerp in 1460, and for several years followed the trade of a blacksmith or farrier, at least till he was in his 20th year. Authors vary in their accounts of the cause of his quitting his first occupation, and attaching himself to the art of painting. Some affirm, that the first unfolding of his genius was occasioned by the sight of a print which accidentally was shown to him by a friend who came to pay him a visit while he was in a declining state of health from the labour of his former employment, and that by his copying the print with some degree of success, he was animated with a desire to learn the art of painting. Others say, he fell in love with a young woman of great beauty, the daughter of a painter, and they allege that love alone wrought the miracle, as he could have no prospect of obtaining her except by a distinguished merit in the profession of painting: for which reason he applied himself with incessant labour to study and practise the art, till he became so eminent as to be intitled to demand her in marriage, and he succeeded. Whatever truth may be in either of these accounts, it is certain that he appeared to have an uncommon genius; his manner was singular, not resembling the manner of any other master, and his pictures were strongly coloured and carefully finished, but yet they have somewhat dry and hard. By many competent judges it was believed, when they observed the strength of expression in some of his compositions, that if he had studied in Italy to acquire some knowledge of the antiques and the great masters of the Roman school, he would have proved one of the most eminent painters of the Low Countries. But he only imitated ordinary life; and seemed more inclined, or at least more qualified, to imitate the defects than the beauties of nature. Some historical compositions of this master deserve commendation; particularly a descent from the cross, which is in the cathedral at Antwerp; and it is justly admired for the spirit, skill, and delicacy of the whole. But the most remarkable and best known picture of Matsys, is that of the two misers in the gallery at Windsor. He died in 1529. He had a son, John; who painted in the same style and manner, but not with a reputation equal to his father; though many of his pictures are sold to unskilful purchasers for the paintings of Quintin. His most frequent subject was the representation of misers counting their gold, or bankers examining and weighing it.

MATT, in a ship, is a name given to rope-yarn, junk, &c. beat flat and interwoven; used in order to preserve the yards from galling or rubbing in hoisting or lowering them.

MATTER, in common language, is a word of the same import with *body*, and denotes that which is tan-

gible, visible, and extended; but among philosophers it signifies that substance of which all bodies are composed; and in this sense it is synonymous with the word *ELEMENT*.

It is only by the senses that we have any communication with the external world; but the immediate objects of sense, philosophers have in general agreed to term *qualities*, which they conceive as inhering in something which is called their *subject* or *substratum*. It is this substratum of sensible qualities which, in the language of philosophy, is denominated *matter*; so that *matter* is not that which we immediately see or handle, but the *concealed subject* or *support* of visible and tangible qualities. What the moderns term *qualities*, was by Aristotle and his followers called *form*; but so far as the two doctrines are intelligible, there appears to be no essential difference between them. From the moderns we learn, that body consists of *matter* and *qualities*; and the Peripatetics taught the same thing, when they said that body is composed of *matter* and *form*.

How philosophers were led to analyse body into matter and form, or, to use modern language, into matter and qualities; what kind of existence they attribute to each; and whether *matter* must be conceived as self-existent or created—are questions which shall be considered afterwards (See METAPHYSICS). It is sufficient here to have defined the term.

MATTHEW, or Gospel of St MATTHEW, a canonical book of the New Testament.

St MATTHEW wrote his gospel in Judæa, at the request of those he had converted; and it is thought he began in the year 41, eight years after Christ's resurrection. It was written, according to the testimony of all the ancients, in the Hebrew or Syriac language; but the Greek version, which now passes for the original, is as old as the apostolical times.

St MATTHEW the Evangelist's Day, a festival of the Christian church, observed on September 21st.

St MATTHEW, the son of Alphaeus, was also called *Levi*. He was of Jewish original, as both his names discover, and probably a Galilean. Before his call to the apostolate, he was a publican or toll-gatherer to the Romans: an office of bad repute among the Jews, on account of the covetousness and exaction of those who managed it; St Matthew's office particularly consisting in gathering the customs of all merchandize that came by the sea of Galilee, and the tribute that passengers were to pay who went by water. And here it was that Matthew sat at the receipt of custom, when our Saviour called him to be a disciple. It is probable, that, living at Capernaum, the place of Christ's usual residence, he might have some knowledge of him before he was called. Matthew immediately expressed his satisfaction in being called to this high dignity, by entertaining our Saviour and his disciples at a great dinner at his own house, whither he invited all his friends, especially those of his own profession, hoping, probably, that they might be influenced by the company and conversation of Christ. St Matthew continued with the rest of the apostles till after our Lord's ascension. For the first eight years afterwards, he preached in Judæa. Then he betook himself to propagating the gospel among the Gentiles.

Mathew.

Matthew
Mattiacum

Gentiles, and chose *ATHIAS* as the scene of his apostolical ministry; where it is said he suffered martyrdom, but by what kind of death is altogether uncertain. It is pretended, but without any foundation, that Hyrtacus, king of Ethiopia, desiring to marry Iphigenia, the daughter of his brother and predecessor *Æglippus*, and the apostle having represented to him that he could not lawfully do it, the enraged prince ordered his head immediately to be cut off. Baronius tells us, the body of St Matthew was transported from Ethiopia to Bithynia, and from thence was carried to Salerno in the kingdom of Naples in the year 954, where it was found in 1080, and where duke Robert built a church bearing his name.

ST MATTHEW, a town of Spain, in the kingdom of Arragon, situate in a pleasant plain, and in a very fertile country watered with many springs. W. Long. c. 16. N. Lat. 40. 22.

MATTHEW of Paris. See *PARIS*.

MATTHEW of Westminster, a Benedictine monk and accomplished scholar, who wrote a history from the beginning of the world to the end of the reign of Edward I. under the title of *Flores Historiarum*; which was afterwards continued by other hands. He died in 1380.

St *MATTHIAS*, an apostle, was chosen instead of Judas. He preached in Judæa and part of *Æthiopia*, and suffered martyrdom. See the *Acts of the Apostles*, chap. i. There was a gospel published under Matthias's name, but rejected as spurious; as likewise some traditions, which met with the same fate.

St Matthias's Day; a festival of the Christian church, observed on the 24th of February. St Matthias was an apostle of Jesus Christ, but not of the number of the twelve chosen by Christ himself. He obtained this high honour upon a vacancy made in the college of the apostles by the treason and death of Judas Iscariot. The choice fell on Matthias by lot; his competitor being Joseph called *Barabas*, and surnamed *Justus*. Matthias was qualified for the apostleship, by having been a constant attendant upon our Saviour all the time of his ministry. He was, probably, one of the 70 disciples. After our Lord's resurrection, he preached the gospel first in Judæa. Afterwards it is probable he travelled eastwards, his residence being principally near the irruption of the river *Apaurus* and the haven *Hyflus*. The barbarous people treated him with great rudeness and inhumanity; and, after many labours and sufferings in converting great numbers to Christianity, he obtained the crown of martyrdom; but by what kind of death, is uncertain.—They pretend to show the relics of St Matthias at Rome; and the famous abbey of St Matthias near Treves boasts of the same advantage; but doubtless both without any foundation. There was a gospel ascribed to St Matthias; but it was universally rejected as spurious.

MATTIACÆ AQUÆ, or *MATTIACI FONTES*, (anc. geog.), now Wisbaden, opposite to Mentz, in the *Vetervaria*. E. Long. 8. N. Lat. 50. 6.

MATTIACUM, or *MATTIUM*, (anc. geog.), a town of the Mattiaci, a branch of the Catti in Germany. Now Marburg in Hesse. E. Long. 8. 40. N. Lat. 50. 40.

Matthews
Matty.

MATTEWS, the first canonical hour, or the first part of the daily service, in the Roman church.

MATTHIOLUS (Peter Andrew), an eminent physician in the 16th century, born at Sienna, was well skilled in the Greek and Latin tongues. He wrote learned commentaries on *Dioscorides*, and other works which are esteemed; and died in 1577.

MATURANT'S, in pharmacy, medicines which promote the supuration of tumors.

MATY (Matthew), M. D. an eminent physician and polite writer, was born in Holland in the year 1718. He was the son of a clergyman, and was originally intended for the church; but in consequence of some mortifications his father met with from the synod, on account of some particular sentiments he entertained about the doctrine of the Trinity, turned his thoughts to physic. He took his degree of M. D. at Leyden; and in 1740 came to settle in England, his father having determined to quit Holland for ever. In order to make himself known, in 1749 he began to publish in French an account of the productions of the English press, printed at the Hague under the name of the *Journal Britannique*. This journal, which continues to hold its rank amongst the best of those which have appeared since the time of Bayle, answered the chief end he intended by it, and introduced him to the acquaintance of some of the most respectable literary characters of the country he had made his own. It was to their active and uninterrupted friendship he owed the places he afterwards possessed. In 1758 he was chosen fellow; and in 1765, on the resignation of Dr Birch, who died a few months after and made him his executor, secretary to the royal society. He had been appointed one of the under librarians of the British museum at its first institution in 1753, and became principal librarian at the death of Dr Knight in 1772. Useful in all these posts, he promised to be eminently so in the last, when he was seized with a languishing disorder, which in 1776 put an end to a life which had been uniformly devoted to the pursuit of science and the offices of humanity. He was an early and active advocate for inoculation; and when there was a doubt entertained that one might have the small-pox this way a second time, tried it upon himself unknown to his family. He was a member of the medical club (with the Drs Parsons, Templeman, Fothergill, Watson, and others), which met every fortnight in St Paul's churchyard. He was twice married, viz. the first time to Mrs Elizabeth Boisragon; and the second to Mrs Mary Deners. He left a son and three daughters. He had nearly finished the *Memoirs of the Earl of Chesterfield*; which were completed by his son-in-law Mr Justamond, and prefixed to that nobleman's *Miscellaneous Works*, 1777, 2 vols 4to.

MATY (Paul Henry), M. A. F. R. S. son of the former, was educated at Westminster and Trinity college Cambridge, and had his travelling fellowship for three years. He was afterwards chaplain to Lord Stormont at Paris in 17... and soon after vacated his next fellowship by marrying one of the three daughters of Joseph Clark, Esq; sister of the late Captain Charles Clark (who succeeded to the command on the death of Captain Cook). On his father's death in 1776, he succeeded to the office of one of the under librarians of

Maty
||
Maupertuis.

of the British museum, and was afterwards preferred to a superior department, having the care of the antiquities, for which he was eminently well qualified. In 1776 he also succeeded his father in the office of secretary to the royal society. On the disputes respecting the reinstatement of Dr Hutton in the department of secretary for foreign correspondence 1784, Mr Maty took a warm and distinguished part, and resigned the office of secretary; after which he undertook to assist gentlemen or ladies in perfecting their knowledge of the Greek, Latin, French, and Italian classes. Mr Maty was a thinking conscientious man; and having conceived some doubts about the articles he had subscribed in early life, he never could be prevailed upon to place himself in the way of ecclesiastical preferment, though his connections were amongst those who could have served him essentially in this point; and soon after his father's death he withdrew himself from ministering in the established church, his reasons for which he published in the 47th volume of the *Genl. Magazine*, p. 466. His whole life was thence forwards taken up in literary pursuits. He received 100*l.* from the duke of Marlborough, with a copy of that beautiful work the *Gemma Marburienses*, of which only 100 copies were worked off for presents; and of which Mr Maty wrote the French account, as Mr Bryant did the Latin. In January 1782 he set on foot a *Review* of publications, principally foreign, which he carried on, with great credit to himself and satisfaction to the public, for near five years, when he was obliged to discontinue it from ill health. He had long laboured under an asthmatic complaint, which at times made great ravages in his constitution, and at last put a period to his life in Jan. 1787, at the age of 42; leaving behind him one son.—Mr Maty enjoyed a respectable rank in the republic of letters, and by his talents and attainments was fully intitled to it. He was eminently acquainted with ancient and modern literature, and particularly conversant in critical researches. The purity and probity of his nature were unquestionable; and his humanity was as exquisite as it would have been extensive, had it been seconded by his fortune.

MAUCAUCO, MACACO, or *Maki*, in zoology. See *LEMUR*, n° 4.

MAVIS, in ornithology, a species of *turdus*. See *TURDUS*.

MAUBEUGE, a town of the Netherlands, in Hainault, with an illustrious abbey of canonesses, who must be noble both by the father and mother's side. This place was ceded to France in 1678; and fortified after the manner of Vauban. It is seated on the river Sambre, in E. Long. 5. o. N. Lat. 50. 15.

MAUNCH, in heraldry, the figure of an ancient coat sleeve, borne in many gentlemen's escutcheons.

MAUNDY THURSDAY, is the Thursday in Passion week; which was called *Maudy* or *Mandate Thursday*, from the command which our Saviour gave his apostles to commemorate him in the Lord's supper, which he this day instituted; or from the new commandment which he gave them to love one another, after he had washed their feet as a token of his love to them.

MAUPERTUIS (Peter Louis Moreau de), a celebrated French academician, was born at St Malo in 1698; and was there privately educated till he arrived

Maupertuis.

at his 16th year, when he was placed under the celebrated professor of philosophy M. le Blond, in the college of la Marche, at Paris. He soon discovered a passion for mathematical studies, and particularly for geometry. He likewise practised instrumental music in his early years with great success; but fixed on no profession till he was 20, when he entered into the army. He first served in the Grey Mousquetaers; but in the year 1720, his father purchased him a company of cavalry in the regiment of La Roche Guyon. He remained but five years in the army, during which time he pursued his mathematical studies with great vigour; and it was soon remarked by M. Freret and other academicians, that nothing but geometry could satisfy his active soul and unbounded thirst for knowledge. In the year 1723, he was received into the Royal Academy of Sciences, and read his first performance, which was a memoir upon the construction and form of musical instruments, November 15. 1724. During the first years of his admission he did not wholly confine his attention to mathematics; he dived into natural philosophy, and discovered great knowledge and dexterity in observations and experiments upon animals. If the custom of travelling into remote climates, like the sages of antiquity, in order to be initiated into the learned mysteries of those times, had still subsisted, no one would have conformed to it with greater eagerness than M. de Maupertuis. His first gratification of this passion was to visit the country which had given birth to Newton; and during his residence at London he became as zealous an admirer and follower of that philosopher as of any one of his own countrymen. His next excursion was to Basil in Switzerland, where he formed a friendship with the famous John Bernoulli and his family, which continued to his death. At his return to Paris, he applied himself to his favourite studies with greater zeal than ever:—And how well he fulfilled the duties of an academician, may be gathered by running over the memoirs of the academy from the year 1724 to 1736; where it appears that he was neither idle nor occupied by objects of small importance. The most sublime questions in geometry and the relative sciences received from his hands that elegance, clearness, and precision, so remarkable in all his writings. In the year 1736, he was sent by the king of France to the polar circle, to measure a degree in order to ascertain the figure of the earth, accompanied by Messrs Clairault, Camus, Le Monnier, l'Abbé Outhier, and Celsius the celebrated professor of astronomy at Upsal. This distinction rendered him so famous, that, at his return, he was admitted a member of almost every academy in Europe.

In the year 1740 Maupertuis had an invitation from the king of Prussia to go to Berlin; which was too flattering to be refused. His rank among men of letters had not wholly effaced his love for his first profession, namely, that of arms. He followed his Prussian majesty into the field, and was a witness of the dispositions and operations that preceded the battle of Moltwitz; but was deprived of the glory of being present, when victory declared in favour of his royal patron, by a singular kind of adventure. His horse, during the heat of the action, running away with him, he fell into the hands of the enemy; and was at first

but

Mau-
perts.

but roughly treated by the Austrian soldiers, to whom he could not make himself known for want of language; but being carried prisoner to Vienna, he received such honours from their imperial majesties as were never effaced from his memory. From Vienna he returned to Berlin; but as the reform of the academy which the king of Prussia then meditated was not yet mature, he went again to Paris, where his affairs called him, and was chosen in 1742 director of the academy of sciences. In 1743 he was received into the French academy; which was the first instance of the same person being a member of both the academies at Paris at the same time. M. de Maupertuis again assumed the soldier at the siege of Fribourg, and was pitched upon by marshal Cigny and the count d'Argenson to carry the news to the French king of the surrender of that citadel.

He returned to Berlin in the year 1744, when a marriage was negotiated and brought about, by the good offices of the queen-mother, between our author and mademoiselle de Borck, a lady of great beauty and merit, and nearly related to M. de Borck at that time minister of state. This determined him to settle at Berlin, as he was extremely attached to his new spouse, and regarded this alliance as the most fortunate circumstance of his life.

In the year 1746, M. de Maupertuis was declared by his Prussian majesty president of the royal academy of sciences at Berlin, and soon after by the same prince was honoured with the order of Merit: However, all these accumulated honours and advantages, so far from lessening his ardour for the sciences, seemed to furnish new allurements to labour and application. Not a day passed but he produced some new project or essay for the advancement of knowledge. Nor did he confine himself to mathematical studies only: metaphysics, chemistry, botany, polite literature, all shared his attention, and contributed to his fame. At the same time, he had, it seems, a strange inquietude of spirit, with a dark atrabilaire humour, which rendered him miserable amidst honours and pleasures. Such a temperament did not promise a very pacific life; and he was engaged in several quarrels. He had a quarrel with Koenig the professor of philosophy at Franeker, and another more terrible with Voltaire. Maupertuis had inserted into the volume of *Memoirs of the Academy of Berlin* for 1746, a discourse upon the laws of motion; which Koenig was not content with attacking, but attributed to Leibnitz. Maupertuis, stung with the imputation of plagiarism, engaged the academy of Berlin to call upon him for his proof; which Koenig failing to produce, he was struck out of the academy, of which he was a member. Several pamphlets were the consequence of this; and Voltaire, for some reason or other, engaged against Maupertuis. We say, for some reason or other: because Maupertuis and Voltaire were apparently upon the most amicable terms; and the latter respected the former as his master in the mathematics. Voltaire, however, exerted all his wit and satire against him; and on the whole was so much transported beyond what was thought right, that he found it expedient in 1753 to quit the court of Prussia.

Our philosopher's constitution had long been considerably impaired by the great fatigues of various kinds
N^o 193.

Mau-
perts.

in which his active mind had involved him; though from the amazing hardships he had undergone in his northern expedition, most of his future bodily sufferings may be traced. The intense sharpness of the air could only be supported by means of strong liquors; which helped but to lacerate his lungs, and bring on a spitting of blood, which began at least 12 years before he died. Yet still his mind seemed to enjoy the greatest vigour; for the best of his writings were produced, and most sublime ideas developed, during the time of his confinement by sickness, when he was unable to occupy his prefdial chair at the academy. He took several journeys to St Malo, during the last years of his life, for the recovery of his health: And though he always received benefit by breathing his native air, yet still, upon his return to Berlin, his disorder likewise returned with greater violence.—His last journey into France was undertaken in the year 1757; when he was obliged, soon after his arrival there, to quit his favourite retreat at St Malo, on account of the danger and confusion which that town was thrown into by the arrival of the English in its neighbourhood. From thence he went to Bourdeaux, hoping there to meet with a neutral ship to carry him to Hamburg, in his way back to Berlin; but being disappointed in that hope, he went to Toulouse, where he remained seven months. He had then thoughts of going to Italy, in hopes a milder climate would restore him to health; but finding himself grow worse, he rather inclined towards Germany, and went to Neuchatel, where for three months he enjoyed the conversation of Lord Marischal, with whom he had formerly been much connected. At length he arrived at Basil, October 16. 1758, where he was received by his friend Bernouilli and his family with the utmost tenderness and affection. He at first found himself much better here than he had been at Neuchatel; but this amendment was of short duration; for as the winter approached, his disorder returned, accompanied by new and more alarming symptoms. He languished here many months, during which he was attended by M. de la Coudamie; and died in 1759.

He wrote in French, 1. The figure of the earth determined. 2. The measure of a degree of the meridian. 3. A discourse on the parallax of the moon. 4. A discourse on the figure of the stars. 5. The elements of geography. 6. Nautical astronomy. 7. Elements of astronomy. 8. A physical dissertation on a white inhabitant of Africa. 9. An essay on cosmography. 10. Reflections on the origin of languages. 11. An essay on moral philosophy. 12. A letter on the progress of the sciences. 13. An essay on the formation of bodies. 14. An eulogium on M. de Montequieu. 15. Letters, and other works.

MAUR (St), was a celebrated disciple of St Benedict. If we can believe a life of St Maur ascribed to Faustus his companion, he was sent by Benedict on a mission to France. But this life is considered as apocryphal. In rejecting it, however, as well as the circumstances of the mission, we must beware of denying the mission itself. It is certain that it was believed in France as early as the 9th century; and notwithstanding the silence of Bede, Gregory of Tours, and others, there are several documents which prove this, or at least render it extremely probable. A celebrated society

Mauriceau
Maurice.

Maurice.

ciety of benedictines took the name of *St Maur* in the beginning of the last century, and received the sanction of Pope Gregory XV. in 1621. This society was early distinguished by the virtue and the knowledge of its members, and it still supports the character. There are perhaps fewer eminent men in it than formerly; but this must be ascribed to the levity of the age, and partly to the little encouragement for the researches of learned men. The chief persons of ingenuity which this society has produced are, the Fathers Menard, d'Acheri, Mabillon, Ruinart, Germain, Lami, Montfaucon, Martin, Vaissette, le Nourri, Martianay, Martenne, Maffuet, &c. &c. See *L'Histoire Litteraire de la Congregation de St. Maur*, published at Paris under the title of *Brussels*, in 4to, 1770, by Dom. Tassin.

MAURICEAU (Francis), a French surgeon, who applied himself with great success and reputation to the theory and practice of his art for several years at Paris. Afterwards he confined himself to the disorders of pregnant and lying-in women, and was at the head of all the operators in this way. His *Observations sur la grossesse et sur l'accouchement des femmes, sur leurs maladies, et celles des enfans nouveaux*, 1694, in 4to, is reckoned an excellent work, and has been translated into several languages; German, Flemish, Italian, English: and the author himself translated it into Latin. It is illustrated with cuts. He published another piece or two, by way of supplement, on the same subject; and died at Paris in 1700.

MAURICE (St) commander of the Theban legion, was a Christian, together with the officers and soldiers of that legion, amounting to 6600 men.—This legion received its name from the city Thebes in Egypt, where it was raised. It was sent by Dioclesian to check the Bagaudae, who had excited some disturbances in Gaul. Maurice having carried his troops over the Alps, the emperor Maximian commanded him to employ his utmost exertions to extirpate Christianity. This proposal was received with horror both by the commander and by the soldiers.—The emperor, enraged at their opposition, commanded the legion to be decimated; and when they still declared that they would sooner die than do any thing prejudicial to the Christian faith, every tenth man of those who remained was put to death. Their perseverance excited the emperor to still greater cruelty; for when he saw that nothing could make them relinquish their religion, he commanded his troops to surround them, and cut them to pieces. Maurice, the commander of these Christian heroes, and Exuperus and Candidus, officers of the legion, who had chiefly incited the soldiers to this noble resistance, signalized themselves by their patience and their attachment to the doctrines of the Christian religion. They were massacred, it is believed, at Agaune, in Chablais, the 22d of September 286.—Notwithstanding many proofs which support this transaction, Dubordier, Hottinger, Moyle, Burnet, and Mosheim, are disposed to deny the fact. It is defended, on the other hand, by Hickee an English writer, and by Dom Joseph de Lisle a benedictine monk *de la congregation de Saint Vannes*, in a work of his, intitled, *Defense de la Verité du Martyre de la Legion Thebaine*, 1737. In defence of the same fact, the

Vol. X. Part II.

reader may consult *Historia di S. Mauricii*, by P. Rofignole a Jesuit, and the *Acta Sanctorum* for the month of September. The martyrdom of this legion, written by St Eucherius bishop of Lyons, was transmitted to posterity in a very imperfect manner by Surius. P. Chifflet a Jesuit, discovered, and gave to the public, an exact copy of this work. Don Ruinart maintains, that it has every mark of authenticity. St Maurice is the patron of a celebrated order in the kingdom of Sardinia's dominions, created by Emmanuel Philibert duke of Savoy, to reward military merit, and approved by Gregory XIII. in 1772. The commander of the Theban legion must not be confounded with another *St Maurice*, mentioned by Theodoret, who suffered martyrdom at Apamea, in Syria.

MAURICE (Mauritius Tiberius), was born at Arabisus in Cappadocia, A. D. 539. He was descended from an ancient and honourable Roman family.—After he had filled several offices in the court of Tiberius Constantine, he obtained the command of his armies against the Persians. His gallantry was so conspicuous, that the emperor gave him his daughter Constantina in marriage, and invested him with the purple the 13th August 582. The Persians still continued to make inroads on the Roman territories, and Maurice sent Philipppicus, his brother-in-law, against them. This general conducted the war with various success. At first he gained several splendid victories, but he did not continue to have a decided superiority. As there was great use for soldiers in these unfortunate times, the emperor issued a mandate in 592, forbidding any soldier to become a monk till he had accomplished the term of his military service. Maurice acquired much glory in restoring Chosroes II. king of Persia, to the throne, after he had been deposed by his subjects. The empire was in his reign harassed by the frequent inroads of the Arabian tribes. He purchased peace from them by granting them a pension nearly equal to 100,000 crowns; but these barbarians took frequent opportunities to renew the war. In different engagements the Romans destroyed 50,000, and took 17,000 prisoners. These were restored, on condition that the king of the Abars should return all the Roman captives in his dominions. Regardless of his promise, he demanded a ransom of 10,000 crowns. Maurice, full of indignation, refused the sum; and the barbarian, equally enraged, put the captives to the sword. While the emperor, to revenge this cruelty, was making preparations against the Abars, Phocas, who from the rank of a centurion had attained the highest military preferment, assumed the purple, and was declared emperor. He pursued Maurice to Chaledon, took him prisoner, and condemned him to die. The five sons of this unfortunate prince were massacred before his eyes; and Maurice, humbling himself under the hand of God, was heard to exclaim, *Thou art just, O Lord, and thy judgments are without partiality*. He was beheaded on the 26th November 602, in the 63d year of his age and 20th of his reign. Many writers have estimated the character of this prince by his misfortunes instead of his actions. They believed him guilty without evidence, and condemned him without reason. It cannot be denied, however, that he allowed Italy to be harassed, but he was a father to the rest of the empire. He re-

Maurice.

stored the military discipline, humbled the pride of his enemies, supported the Christian religion by his laws, and piety by his example. He loved the sciences, and was the patron of learned men.

MAURICE, elector of Saxony, son of Henry le Pieux, was born A. D. 1521. He was early remarkable for his courage, and during his whole life he was engaged in warlike pursuits. He served under the emperor Charles V. in the campaign of 1544 against France; and in the year following against the league of Smalkalde; with which, although a Protestant, he would have no manner of connection. The emperor, as a reward for his services, in the year 1547, made him elector of Saxony, having deprived his cousin John Frederick of that electorate. Ambition had led him to second the views of Charles, in the hope of being elector, and ambition again detached him from that prince. In 1551 he entered into a league against the emperor, together with the elector of Brandenburg, the Count Palatine, the duke of Wirtemberg, and many other princes. This league, encouraged by the young and enterprising Henry II. of France, was more dangerous than that of Smalkalde. The pretext for the association was the deliverance of the Landgrave of Hesse, whom the emperor kept prisoner. Maurice and the confederates marched, in 1552, to the desiles of Tirol, and put to flight the Imperial troops who guarded them. The emperor and his brother Ferdinand narrowly escaped, and fled from the conquerors in great disorder. Charles having retired into Passau, where he had collected an army, brought the princes of the league to terms of accommodation. By the famous peace of Passau, which was finally ratified the 12th of August 1552, the emperor granted an amnesty without exception to all those who had carried arms against him from the year 1546. The Protestants not only obtained the free exercise of their religion, but they were admitted into the imperial chamber, from which they had been excluded since the victory of Mulberg.—Maurice soon after united himself with the emperor against the Margrave of Brandenburg, who laid waste the German provinces. He engaged him in 1553, gained the battle of Sivershausen, and died of the wounds he had received in the engagement two days after. He was one of the greatest protectors of the Lutherans in Germany, and a prince equally brave and politic. After he had profited by the spoils of John Frederick, the chief of the Protestants, he became himself the leader of the party, and by these means maintained the balance of power against the emperor in Germany.

MAURICE de Nassau, prince of Orange, succeeded to the government of the Low Countries after the death of his father William, who was killed in 1584 by the fanatic Gerard. The young prince was then only eighteen years of age, but his courage and abilities were above his years. He was appointed captain general of the United Provinces, and he reared that edifice of liberty of which his father had laid the foundation. Breda submitted to him in 1590; Zutphen, Deventer, Hulst, Nimwegen, in 1591. He gained several important advantages in 1592, and in the year following he made himself master of Gertrudenburg. When he had performed these splendid services, he returned to the Low Countries by the way

Maurice.

of Zealand. His fleet was attacked by a dreadful tempest, in which he lost forty vessels, and he himself had very nearly perished. His death would have been considered by the Hollanders as a much greater calamity than the loss of their vessels. They watched over his safety with exceeding care. In 1594, one of his guards was accused of an intention to take away his life; and it was generally believed that he was bribed to this service by the enemies of the republic. He fell a sacrifice at Bruges, either to his own fanaticism or to the jealous anxiety of the friends of Maurice. The prince of Orange, increasing in reputation, defeated the troops of the archduke Albert in 1597, and drove the Spaniards entirely out of Holland. In 1600 he was obliged to raise the siege of Dunkirk; but he took ample vengeance on Albert, whom he again defeated in a pitched battle near Newport. Before the action, this great general sent back the ships which had brought his troops into Flanders: *My brethren* (said he to his army), *we must conquer the enemy or drink up the waters of the sea. Determine for yourselves; I have determined I shall either conquer by your bravery, or I shall never survive the disgrace of being conquered by men in every respect our inferiors.* This speech elevated the soldiers to the highest pitch of enthusiasm, and the victory was complete. Rhinberg, Grave, and Ecluse, cities in Flanders, submitted to the conqueror the following year. Maurice, however, not only laboured for the commonwealth, but also for himself. He coveted the sovereignty of Holland, and was opposed in the prosecution of his design by the pensioner Barneveldt. The zeal and activity of this wise republican cost him his life. He was an Arminian; and at this time Maurice defended Gomar against Arminius.—Taking advantage of the general odium under which the Arminians lay, he found means to get Barneveldt condemned in 1619. His death, wholly owing to the cruel ambition of the prince of Orange, made a deep impression on the minds of the Hollanders. The truce with Spain being expired, Spinola laid siege to Breda in 1624, and in six months, by the proper direction of his great talents, though with great slaughter of his troops, he took the place. The prince of Orange, unsuccessful in every attempt to raise the siege, died of vexation in 1625, aged 55 years, with the reputation of the greatest warrior of his time.—“The life of this Stadtholder (says the Abbé Raynal) was almost an uninterrupted series of battles, of sieges, and of victories. Of moderate abilities in every thing else, he shone conspicuous in his military capacity. His camp was the school of Europe, and those who received their military education in his armies augmented, perhaps, the glory of their master.—Like Montecuculi, he discovered inimitable skill in his marches and encampments; like Vauban, he possessed the talent of fortifying places, and of rendering them impregnable; like Eugene, the address of finding subsistence for great armies, in countries barren by nature, or ravaged by war; like Vendome, the happy talent of calling forth, in the moment they became necessary, greater exertions from his soldiers than could reasonably be expected; like Conde, that insupportable quickness of eye which decides the fortune of battles; like Charles XII. the art of rendering his troops almost invincible to cold, hunger, and fatigue; like Turenne, the secret of making war with the least possible

possible

Mauritania sible expence of human blood." The Chevalier Folard maintains, that Maurice was the greatest commander of infantry since the time of the Romans. He studied the military art of the ancients, and applied their rules with great exactness in the various occurrences of war. He not only took advantage of the inventions of others, but he enriched the science of war with several improvements. Telescopes were first used by him for a military purpose; and, besides a kind of gallery in conducting a siege, and the plan of blockading a strong place, which were of his invention, he greatly improved the whole art by his method of pushing an attack with great vigour, and of defending, for the greatest length of time, and in the best manner, a place besieged. In short, the many useful things which he practised or invented, placed him in the highest rank among men of a military character. On one occasion, a lady of quality asked him, *who was the first general of the age?* Spinola (replied he) *is the second.* It was his constant practice, during sleep, to have two guards placed by his bedside, not only to defend him in case of danger, but to awake him if there should be the least occasion. The war betwixt Spain and Holland was never carried on with greater keenness and animosity than during his administration.—The Grand Signior, hearing of the vast torrents of blood shed in this contest, thought that a great empire must depend on the decision. The object of so many battles was pointed out to him on a map, and he said coldly, *If it were my business, I would send my pioneers, and order them to cast this little corner of earth into the sea.* Maurice, like many great men, was impatient under contradiction, and too much devoted to women. He was succeeded by Frederic Henry his brother.

MAURITANIA, an ancient kingdom of Africa, bounded on the west by the Atlantic ocean, on the south by Getulia or Lybia Interior, and on the north by the Mediterranean, and comprehending the greater part of the kingdoms of Fez and Morocco.—Its ancient limits are not exactly mentioned by any historian; neither can they now be ascertained by any modern observations, these kingdoms being but little known to Europeans.

This country was originally inhabited by a people called *Mauri*, concerning the etymology of which name authors are not agreed. It is probable, however, that this country, or at least a great part of it, was first called *Phut*, since it appears from Pliny, Ptolemy, and St Jerom, that a river and territory not far from Mount Atlas went by that name. From the Jerusalem Targum it likewise appears, that part of the *Mauri* may be deemed the offspring of Lud the son of Misraim, since his descendants, mentioned Genesis x. are there called מורי, *Mauri*; or *Mauritani*. It is certain, that this region, as well as the others to the eastward of it, had many colonies planted in it by the Phenicians. Procopius tells us, that in his time two pillars of white stone were to be seen there, with the following inscription in the Phenician language and character, upon them: "We are the *Canaenites*, that fled from *Jehua* the son of Nun, that notorious robber." *Ibn Rachib*, or *Ibn Rachib*, an African writer cited by Leo, together with Evagrius and Nicephorus Callistus, assert the same thing.

The Mauritians, according to Ptolemy, were *Mauritania* divided into several cantons or tribes. The *Metagonites* were seated near the straits of Hercules, now those of Gibraltar. The *Sacefis*, or *Cocfis*, occupied the coast of the Iberian sea. Under these two petty nations the *Majices*, *Verrus*, and *Verbice* or *Verrice*, were settled. The *Sulfe*, or *Salmis*, were situated lower, towards the ocean; and, still more to the south, the *Volubilians*. The *Maurenfi* and *Hepiditani* possessed the eastern part of this country, which was terminated by the *Mulucha*. The *Angaucani* or *Jangaucuani*, *Nesiberes*, *Zagrenfi*, *Baniube*, and *Vacutæ*, extended themselves from the southern foot of Ptolemy's Atlas Minor to his Atlas Major. Pliny mentions the *Baniure*, whom Father Hardouin takes to be Ptolemy's *Baniubæ*; and *Mela* the *Atlantes*, whom he represents as possessed of the western parts of this district.

The earliest prince of Mauritania mentioned in history is Neptune; and next to him were Atlas and Antæus his two sons, both famous in the Grecian fables on account of their wars with Hercules. Antæus, in his contention with that hero, seems to have behaved with great bravery and resolution. Having received large reinforcements of Libyan troops, he cut off great numbers of Hercules's men. But that celebrated commander, having at last intercepted a strong body of Libyans sent to the relief of Antæus, gave him a total overthrow, wherein both he and the best part of his forces were put to the sword. This decisive action put Hercules in possession of Libya and Mauritania, and consequently of the riches of all these kingdoms. Hence came the fable, that Hercules, finding Antæus, a giant of an enormous size with whom he was engaged in single combat, to receive fresh strength as often as he touched his mother earth when thrown upon her, at last lifted him up in the air and squeezed him to death. Hence likewise may be deduced the fable intimating that Hercules took the globe from Atlas upon his own shoulders, overcame the dragon that guarded the orchards of the Hesperides, and made himself master of all the golden fruit there. Bochart thinks that the fable alluded chiefly to naval engagements, wherein Hercules, for the most part, was victorious; though Antæus from time to time received succours by sea. But at last Hercules, coming up with one of his squadrons which had a strong reinforcement on board, made himself master of it, and thus rendered Antæus incapable for the future of making head against him. The same author likewise insinuates, that the notion of Antæus's gigantic stature prevailing for so many centuries amongst the Tingitani, pointed out the size of the vessels of which his fleets and squadrons were composed. As for the golden apples so frequently mentioned by the old mythologists, they were the treasures that fell into Hercules's hands upon the defeat of Antæus; the Greeks giving the oriental word *malos*, *riches*, the signification affixed to their own term *malos*, *apples*.

With regard to the age in which Atlas and Antæus lived, the most probable supposition seems to be that of Sir Isaac Newton. According to that illustrious author, Ammon the father of Sefac was the first king of Libya, or that vast tract extending from the borders of Egypt to the Atlantic ocean; the conquest

Mauritania

quest of which country was effected by Sefac in his father's life-time. Neptune afterwards excited the Libyans to a rebellion against Sefac, and slew him; and then invaded Egypt under the command of Atlas or Antæus, the son of Neptune, Sefac's brother and admiral. Not long after, Hercules, the general of Thebais and Ethiopia for the gods or great men of Egypt, reduced a second time the whole continent of Libya, having overthrown and slain Antæus near a town in Thebais, from that event called *Antæa* or *Antæopolis*; this, we say, is the notion advanced by Sir Isaac Newton, who endeavours to prove, that the first reduction of Libya, by Sefac, happened a little above a thousand years before the birth of Christ, as the last, by Hercules, did some few years after. Now, though we do not pretend to adopt every particular circumstance of Sir Isaac Newton's system, yet we cannot forbear observing, that it appears undeniably plain from scripture, that neither the western extremity of Libya, nor even the other parts of that region, could possibly have been so well peopled before the time of David or Solomon, as to have sent a numerous army to invade Egypt. For Egypt and Phœnicia, from whence the greatest part of the ancestors of the Libyans came, and which were much nearer the place from whence the first dispersion of mankind was made, could not themselves have been greatly overstocked with inhabitants any considerable time before the reign of Saul. And that such an invasion happened in the reign of Neptune, or at least of his son Antæus, has been most fully evinced by this most excellent chronologer.

From the defeat of Antæus, nothing remarkable occurs in the history of Mauritania till the times of the Romans, who at last brought the whole kingdom under their jurisdiction; for which see the article *ROME*. With regard to the customs, &c. of this people, it would seem, from what Hyginus insinuates, that they fought only with clubs, till one Belus, the son of Neptune, as that author calls him, taught them the use of the sword. Sir Isaac Newton makes this Belus to have been the same person with Sesostris king of Egypt, who over-ran a great part of the then known world. 2. All persons of distinction in Mauritania went richly attired, wearing much gold and silver in their clothes. They took great pains in cleaning their teeth, and curled their hair in a curious and elegant manner. They combed their beards, which were very long, and always had their nails pared extremely close. When they walked out in any numbers, they never touched one another, for fear of disconcerting the curls into which their hair had been formed. 3. The Mauritanian infantry, in time of action, used shields made of elephants skins, being clad in those of lions, leopards, and bears, which they kept on both night and day. 4. The cavalry of this nation was armed with broad short lances, and carried targets or bucklers, made likewise of the skins of wild beasts. They used no saddles. Their horses were small and swift, had wooden collars about their necks, and were so much under the command of their riders, that they would follow them like dogs. The habit of these horsemen was not much different from that of the foot above-mentioned, they constantly wearing a large tunic of the skins of wild beasts. The Phutei,

of whom the Mauritians were a branch, were eminent for their shields, and the excellent use they made of them, as we learn from Homer, Xenophon, Herodotus, and scripture. Nay, Herodotus seems to intimate, that the shield and helmet came from them to the Greeks. 5. Notwithstanding the fertility of their soil, the poorer sort of the Mauritians never took care to manure the ground, being strangers to the art of husbandry; but roved about the country in a wild savage manner, like the ancient Scythians or Arabes Scenitæ. They had tents, or *mapalia*, so extremely small, that they could scarce breathe in them. Their food was corn, herbage, &c. which they frequently did eat green, without any manner of preparation; being destitute of wine, oil, and all the elegancies as well as many necessities of life. Their habit was the same both in summer and winter, consisting chiefly of an old tattered, though thick garment, and over it a coarse rough tunic; which answered probably to that of their neighbours the Numidians. Most of them lay every night upon the bare ground; though some of them strewed their garments thereon, not unlike the present African Kabyles and Arabs, who, according to Dr Shaw, use their hykes for a bed and covering in the night. 6. If the most approved reading of Horace may be admitted, the Mauritians shot poisoned arrows; which clearly intimates, that they had some skill in the art of preparing poisons, and were excellent dartmen. This last observation is countenanced by Herodian and Elian, who entirely come into it, affirming them to have been in such continual danger of being devoured by wild beasts, that they durst not stir out of their tents or *mapalia* without their darts. Such perpetual exercise must render them exceedingly skilful in hurling that weapon. 7. The Mauritians sacrificed human victims to their deities, as the Phœnicians, Carthaginians, &c. did.

The country people were extremely rude and barbarous; but those inhabiting cities must undoubtedly have had at least some smattering in the literature of the several nations they deduced their origin from. That the Mauritians had some knowledge in naval affairs, seems probable, not only from the intercourse they had with the Phœnicians and Carthaginians, as well as the situation of their country; but likewise from Orpheus, or Onomacritus, who asserts them to have made a settlement at the entrance into Colchis, to which place they came by sea. Magic, sorcery, divination, &c. they appear to have applied themselves to in very early times. Cicero and Pliny say, that Atlas was the inventor of astrology and the doctrine of the sphere, i. e. he first introduced them into Mauritania. This, according to Diodorus Siculus, gave rise to the fable of Atlas's bearing the heavens upon his shoulders. The same author relates, that Atlas instructed Hercules in the doctrine of the sphere and astrology, or rather astronomy, who afterwards brought those sciences into Greece.

MAURITIA, the GINKGO, or Maiden-hair tree: A genus of plants belonging to the natural order of Palmæ. The calyx of the male is monophyllous; the corolla monopetalous; with six stamina. It is a native of Japan, where it is also known by the names of *Ginan* and *Iyso*. It rises with a long, erect, thick and branched stem, to the size of a walnut-tree. The bark

Mauritania
Mauritia

Mauritius. bark is ash-coloured, the wood brittle and smooth, the pith soft and fungous. The leaves are large, expanded from a narrow bottom into the figure of a maiden-hair leaf, unequally parted, streaked, without fibres or nerves; both surfaces having the same appearance, and supported upon footstalks, which are compressed upon the upper surface, and extended into the substance of the leaf. From the uppermost footstalk the flowers in long catkins that are filled with the fertilizing powder; and to which succeeds the fruit, adhering to a thick fleshy pedicle, which proceeds from the bottom of the leaves. This fruit is either exactly or nearly round, and of the appearance and size of a damask plum. The substance surrounding the fruit is fleshy, juicy, white, very harsh, and adheres so firmly to the inclosed nut, as not to be separated from it, except by putrefaction. The nut, properly termed *Gineau*, resembles the pistachia nut, especially a Persian species named *bergjes pistai*; but is almost double in size, and of the figure of an apricot stone. The shell is somewhat white, woody, and brittle; and incloses a white loose kernel, having the sweetness of an almond, along with a degree of harshness. These kernels taken after dinner are said to promote digestion, and to give relief in surfeits; whence they never fail to make part of the desert in great feasts and anniversary entertainments.—Many of these plants have been reared by Mr James Gordon at his nursery near Mile-end. They seem to be very hardy, and thrive in this country in the open air.

MAURITIUS, or MAURICE, an island of Africa, about 400 miles east of Madagascar, lying in the latitude of 20 and 21 degrees south. In the beginning of the 16th century it was discovered by the Portuguese, who, knowing that Pliny and other ancient writers had mentioned the island of Cerne in these seas, took it for granted that this must be it; and accordingly we find it styled *Cerne* or *Sirre*, in their maps: but, notwithstanding this, they did not think fit to settle it; and indeed their force was so small, in comparison of the vast dominions they grasped, that it was very excusable. However, according to their laudable custom, they put some hogs, goats, and other cattle upon it, that in case any of their ships either going to the Indies, or returning to Portugal, should be obliged to touch there, they might meet with refreshments. The Dutch, in the second voyage they made to the East Indies under their admiral James Cornelius Vanneck, came together with five ships on the 15th of September 1568; anchored in a commodious port, to which they gave the name of *Warswick Haven*; and gave a very good account of the place in their journals. Captain Samuel Castleton, in the Pearl, an English East India ship, arrived there on the 27th of March 1612; and taking it to be an island undiscovered before, bestowed upon it the name of *England's Forest*, though others of his crew called it *Pearl-Island*, and in the account of their voyage, written by John Tatton the master of the ship, celebrated it as a place very convenient for shipping, either outward or homeward bound, to refresh at. This they sometimes accordingly did, and brought some cargoes of ebony and rich wood from thence, but without fixing any settlement.

At length, in 1638, the Dutch seized themselves

here; and it is highly remarkable, that at the very time they were employed in making their first settlement, the French sent a vessel to take possession of it, who found the Dutch before-hand with them, and refused the assistance of an English Indianman, wooding and watering in another port of the island, who very frankly offered it, to drive the Dutch from their half-settled pests. They continued for some time in quiet possession of the places they fortified in this island, to which they gave the name of *Mauritius*. But having engaged the French, who were settled on Madagascar, to steal 50 of the natives, and sell them for slaves, for the improvement of the Dutch settlements here, this proved the ruin of both colonies: for the negroes surprised and massacred the French in Madagascar; and the slaves in Mauritius fled into the centre of the island; from whence they so much and so incessantly molested those who had been formerly their masters, that they chose to quit a country where they could no longer remain in any tolerable degree of safety. The East India company, however, from motives of convenience, and a very imperfect notion of its value, disapproved this measure, and therefore ordered it to be resettled; which was accordingly done, and three forts erected at the principal havens. Things now went on somewhat better than they did before; but they were still very much disturbed by the revolted negroes in the heart of the isle, whom they could never subdue. One principal use that the company made of this place, was to send thither state-prisoners, who, as they were not men of the best morals, quickly corrupted the rest of the inhabitants, and rendered them such a race of outrageous smugglers, the situation of the place concurring with their bad dispositions, that, after various ineffectual attempts made to reform them, orders were at length given to abandon Mauritius a second time, which, after some delays, were put in execution in the year 1710.

Two years after this, the French took possession of it, and named it the *Isle de France*. This name has obtained among themselves, but the Europeans in general continue to call it Mauritius. It lies in S. Lat. 20. 15. E. Lon. 60 15. The inconveniences arising from the want of a port at the island of Bourbon, induced the French to take possession of Mauritius, it having two very good harbours, to fortify which no expence has been spared. That on the north-west is called *Port Louis*, that on the south-east side of the island is called *Port Bourbon*. The trade-wind from the south-east in these latitudes blows all the year round, excepting for a few days at the summer solstice, when it is interrupted by hard gales and hurricanes from the north. The ease with which this wind enables ships to enter the port of Bourbon, caused the French, when they first took possession of this spot, to esteem it the best port in the island; but experience pointing out to them, that the same wind often rendered the passage out of the harbour so difficult, that a ship was sometimes obliged to wait a considerable time before the weather admitted of her putting to sea, this harbour is in a great measure abandoned, and the principal town and seat of government is now fixed at port Louis, which is nearly in the middle of the north side of the island, and its entrance is through a channel formed by two shoals, which advance about two miles into the sea.

Mauritius,

the sea. When a ship arrives opposite to this channel, the south-east wind hinders her from entering the port under sail, and she must either warp in with cables or be towed in by boats. The necessity of this operation, joined to the extreme narrowness of the channel, which does not admit of two ships abreast of each other entering at the same time, is one of the best defences the harbour has against an attack by sea; for, from these obstacles, an enemy would find it a matter of the greatest difficulty to force the port; and in addition to this natural strength, they have built two forts and as many batteries, which are mounted with heavy cannon, and entirely command the approach to the harbour, should ships presume to force an entry under sail. This port is capable of containing 100 sail of ships, and is well provided with every requisite for repairing and even building of ships. This port has proved of the greatest advantage to France in the several wars which have been carried on between Great Britain and her; and has proved of great utility to the French East India company's commerce; for here their ships and crews were sure to meet with all necessary refreshment after a long voyage. The port of Bourbon is also fortified; and an army landed here would find it an extreme difficult task to pass the mountains to the different parts of the island. There are several places between the north-east extremity and port Louis where boats may land, but all these are defended by batteries; and the country behind them is a continued thicket: The rest of the coast is inaccessible. In the north-eastern quarter is a plain extending about 10 miles from east to west, and in some places five miles inland from the northern coast. All the rest of the island is full of high and steep mountains, lying so near to one another, and the intervals between them so narrow, that, instead of valleys, they rather resemble the beds of torrents; and these are choaked with huge fragments of rocks which have fallen from the steep sides of the impending mountains. On the summits of the mountains ice is frequently to be found, and they are covered with forests of ebony and other large trees. The ground they shade produces herbage, shrubs, and plants of various sorts, from the common grass to the strongest thorn, and that in such profusion, that they form a thicket so closely interwoven, that no progress can be made but by means of a hatchet. Notwithstanding these difficulties, plantations have been formed on these mountains, and very considerable progress has been made in the plains; but the productions, although mostly of the same kind, are not only in less quantity, but of an inferior quality to those produced at Bourbon island.

In a course of years, however, this settlement cost so much, and was considered in every light worth so little, that it had been more than once under deliberation, whether, after the example of the Dutch, they should not leave it again to its old negro inhabitants; which sooner or later in all likelihood would have been its fate, if, in 1735, the famous M. de la Bourdonnais had not been sent thither, with the title of *governor-general of the French islands*.

He found this life in the worst state possible. thinly inhabited by a set of lazy people, who equally hated

industry and peace, and who were continually flatter-Mauritius ing this man to his face, and belying him wherever and as far as they durst. He gave himself no trouble about this, having once found the means to make himself obeyed; he saw the vast importance of the island; he conceived that it might be settled to great advantage; and, without so much as expecting the thanks of those for whom he laboured, he began to execute this great design. His first step was to bring over black boys from Madagascar, whom he carefully trained up in good principles, and in continual exercise; by which he rendered them so good soldiers, that he very quickly obliged the Marones, or wild negroes, either to submit or to quit the island: he taught the planters to cultivate their lands to advantage; he, by an aqueduct, brought fresh water to the sea-side; and whereas they had not so much as a boat at his coming thither, he made a very fine dock, where he not only built sloops and larger vessels, but even a ship of the burden of 500 ton. However incredible it may seem, yet it is certainly fact, that in the space of five years he converted this country into a paradise, that had been a mere wilderness for 5000; and this in spite of the inhabitants, and of the company, who being originally prejudiced by them, behaved ill to him at his return. He soon made the cardinal de Fleury, however, sensible of the true state of things; and compelled the company to acknowledge, though they did not reward, his services. He afterwards returned into the Indies, and perfected the work he had begun, and to him it is owing that the life of France was rendered one of the finest and most important spots upon the globe. Here no coffee is raised; but by the indefatigable industry of M. de Bourdonnais, sugar, indigo, pepper, and cotton (which are not at Bourbon), came to be cultivated with success. Since the departure of that most excellent governor, the plantations have been neglected, and are fallen off; but if a proper spirit of activity was raised among the inhabitants, they might soon be made to resume their flourishing appearance. Mines of iron have been discovered in the mountains near the great plain, in the north-east part of the island; and these mountains affording in great abundance the necessary fuel, forges have been erected: but the iron produced is of a very inferior quality, it being brittle, and only fit for making cannon-balls and bomb-shells. Black cattle, sheep, and goats, are preserved with difficulty; the first generally die before they have been a year in the island, and this occasions frequent importations of them from Madagascar and other parts. Common domestic poultry breed in great plenty; and, with fish and turtle, furnish a great part of the food of the European inhabitants.

The approach to the island is extremely dangerous, it being surrounded with ledges of rocks, and many of them covered by the sea. The shore abounds with coral and shells. This island is said to contain 60 rivers: some are considerable streams, and most of them have their sources from lakes, of which there are several in the middle part of the island. The rivers afford plenty of various kinds of fish, particularly eels. These are of an enormous size, some having been found that were six feet long, and six inches in circumference, and so extremely voracious, that it is dangerous to
bathe

urua
centius
bathe in those parts of the river where they lie, as they will seize a man without fear, and have strength sufficient to keep him under water till he is drowned. Here is a great variety of birds, and bats as large as a young kitten : the inhabitants esteem them a delicate morsel. The air is both hot and moist, but not unwholesome. The place abounds with insects, which are very troublesome ; but there are no serpents. It has been discovered, that off Port Louis the south-east wind generally blows with least strength about sun-rise ; and it also happens, on four or five days, at intervals, in the course of a month, that early in the morning the wind ceases in the northern part of the island for an hour or two, when a breeze rises, although but faintly, from the north-west ; during which, a ship stationed at the entrance of the channel to avail herself of this breeze, may enter the harbour and attack the forts.

MAURUA, one of the Society-Islands in the South Sea. It is a small island, entirely surrounded with a ridge of rocks, and without any harbour for shipping. It is inhabited ; and its productions are the same with those of the neighbouring islands. A high round hill rises in the middle of it, which may be seen at the distance of 10 or 12 leagues.

MAUSOLEUM, a magnificent tomb or funeral monument. The word is derived from Mausolus king of Caria, to whom Artemisia his widow erected a most stately monument, esteemed one of the wonders of the world, and called it, from his own name, *Mausoleum*.

St MAWES, a town of Cornwall, in England, seated on the east side of Falmouth haven, in W. Long. 5. 26. N. Lat. 50. 30. Though but a hamlet of the parish of St Just, two miles off, without a minister, or either church, chapel, or meeting-house, it has sent members to parliament ever since 1562, who are returned by its mayor or portreeve. It consists but of one street, under a hill, and fronting the sea, and its inhabitants subsist purely by fishing. King Henry VIII. built a castle here, over against Pendennis, for the better security of Falmouth haven. It has a governor, a deputy, and two gunners, with a platform of guns. Here is a fair the Friday after St Luke's day.

MAXENTIUS (Marcus Aurelius Valerius), a son of the emperor Maximianus Hercules, was, by the voluntary abdication of Dioclesian, and of his father, raised to the empire, A. D. 306. He afterwards incited his father to re-assume his imperial authority ; and in a perfidious manner destroyed Severus, who had delivered himself into his hands, and relied upon his honour for the safety of his life. His victories and successes were impeded by Galerius Maximianus, who opposed him with a powerful force. The defeat and voluntary death of Galerius soon restored peace to Italy ; and Maxentius passed into Africa, where he rendered himself odious by his cruelty and oppression. He soon after returned to Rome, and was informed that Constantine was come to dethrone him. He gave his adversary battle near Rome, and, after he had lost the victory, he fled back to the city. The bridge over which he crossed the Tiber was in a decayed situation, and he fell into the river, and was drowned, A. D. 312. The cowardice and luxuries of Maxentius were as conspicuous as his cruelties. He

oppressed his subjects with heavy taxes, to gratify the cravings of his pleasures, or the avarice of his favourites. He was debauched in his manners, and neither virtue nor innocence were safe whenever he was inclined to voluptuous pursuits. His body was deformed, and unyielding. To visit a pleasure ground, or to exercise himself under a marble portico, or walk on a shady terrace, was to him a Herculean labour, which required the greatest exertions of strength and resolution.

MAXILLA, the JAW. See ANATOMY, n° 20 —26.

MAXIM, an established proposition or principle ; in which sense it denotes much the same with axiom.

MAXIMILIAN I. emperor of Germany, signalized himself against the French while he was king of the Romans, and after he was emperor entered into the army of Henry VIII. of England as a volunteer against that nation : he was a protector of learned men, and abolished an iniquitous tribunal, styled *Judicium oculum Westphalie* : he composed some poems, and the memoirs of his own life. He died in 1519, aged 60.

MAXIMUM, in mathematics, denotes the greatest quantity attainable in any given case.

If a quantity conceived to be generated by motion increases or decreases till it arrives at a certain magnitude or position, and then, on the contrary, grows greater or lesser, and it be required to determine the said magnitude or position, the question is called a *problem de maximis et minimis*.

MAXIMUS, a celebrated Cynic philosopher, and magician of Ephesus. He instructed the emperor Julian in magic ; and, according to the opinion of some historians, it was in the conversation and company of Maximus that the apostasy of Julian originated. The emperor not only visited the philosopher, but he even submitted his writings to his inspection and censure. Maximus refused to live in the court of Julian, and the emperor, not dissatisfied with the refusal, appointed him high pontiff in the province of Lydia, an office which he discharged with the greatest moderation and justice. When Julian went into the east, the philosopher promised him success, and even said that his conquests would be more numerous and extensive than those of the son of Philip. He persuaded his imperial pupil, that, according to the doctrine of Metempsychosis, his body was animated by the soul which once animated the hero whose greatness and victories he was going to eclipse. After the death of Julian, Maximus was almost sacrificed to the fury of the soldiers ; but the interposition of his friends saved his life, and he retired to Constantinople. He was soon after accused of magical practices, before the emperor Valens, and beheaded at Ephesus, A. D. 366. He wrote some philosophical and rhetorical treatises, some of which were dedicated to Julian. They are all now lost.

MAXIMUS of Tyre, a Platonic philosopher, went to Rome in 146, and acquired such reputation there, that the emperor Marcus Aurelius became his scholar, and gave him frequent proofs of his esteem. This philosopher is thought to have lived till the reign of the emperor Commodus. There are still extant 41 of his dissertations ; a good edition of which was printed by Daniel

Maxilla.
Maximus.

Maximus, Daniel Heinfius, in 1624, in Greek and Latin, with notes.

MAXIMUS MARIUS. See *MARIUS*.

MAXIMUS (St), an abbot and confessor of the 7th century, was of a noble family of Constantinople, and distinguished himself by his zeal against the Monothelites, for which he was thrown into prison, and died there on the 13th of August 1662. Hewrote a Commentary on the books attributed to Dionysius the Areopagite, and several other works, of which an edition has been published by father Combefis.

MAY, the fifth month in the year, reckoning from our first, or January; and the third, counting the year to begin with March, as the Romans anciently did. It was called *Maius* by Romulus, in respect to the senators and nobles of his city, who were named *maiores*; as the following month was called *Junius*, in honour of the youth of Rome, in *honorem juniorum*, who served him in the war; though some will have it to have been thus called from *Maius*, the mother of Mercury, to whom they offered sacrifice on the first day of it; and Papias derives it from *Medius: eo quod tunc terra maderet*. In this month the sun enters Gemini, and the plants of the earth in general begin to flower.—The month of May has ever been esteemed favourable to love; and yet the ancients, as well as many of the moderns, look on it as an unhappy month for marriage. The original reason may perhaps be referred to the feast of the Lemures, which was held in it. Ovid alludes to this in the fifth of his *Fasts*, when he says,

*Nec vidua tediis eadem, nec virginis apta
Tempora; quæ nuptiæ, non diuturna fuit;
Hæc quoque de causa, si te proverbia tangunt,
Mense malum Maio nubere vulgus ait.*

May-dew. See *Dew*.

May-duke, a species of cherry. See *PRUNUS*.

MAY (Isle of), a small island at the mouth of the Frith of Forth, in Scotland, about a mile and an half in circumference, and seven miles from the coast of Fife, almost opposite to the rock called the *Bass*. It formerly belonged to the priory of Pittenweem; and was dedicated to St Adrian, supposed to have been martyred in this place by the Danes; and hither, in times of Popish superstition, barren women used to come and worship at his shrine, in hopes of being cured of their sterility. Here is a tower and light-house built by Mr Cunningham of Barns, to whom king Charles I. granted the island in fee, with power to exact two-pence per ton from every ship that passes, for the maintenance of a light-house. In the middle of it there is a fresh-water spring, and a small lake. The soil produces pasturage for 100 sheep and 20 black cattle. On the west side the steep rocks render it inaccessible; but to the east there are four landing-places and good riding. It was here that the French Squadron, having the chevalier de St George on board, anchored in the year 1708, when the vigilance of Sir George Byng obliged him to relinquish his design, and bear away for Dunkirk. The shores all round the island abound with fish, and the cliffs with water-fowl.

MAY (Thomas), an eminent English poet and historian in the 17th century, was born of an ancient but decayed family in Suffex, educated at Cambridge, and

Nº 198.

afterwards removed to London, where he contracted a friendship with several eminent persons, and particularly with Endymion Porter, Esq; one of the gentlemen of the bed-chamber to king Charles I. While he resided at court, he wrote the five plays now extant under his name. In 1622, he published a translation of Virgil's *Georgics*, with annotations; and in 1633 a poem on king Edward III. and a translation of Lucan's *Pharsalia*, which poem he continued down to the death of Julius Cæsar, both in Latin and English verse. Upon the breaking out of the civil war he adhered to the parliament; and in 1647, he published, "The history of the parliament of England, which began November the third MDCXL. With a short and accessary view of some precedent years." In 1649, he published, *Historia parlamenti Angliæ Breviarium*, in three parts; which he afterwards translated into English. He wrote the History of Henry II. in English verse. He died in 1652. He went well to rest over-night, after a cheerful bottle as usual, and died in his sleep before morning; upon which his death was imputed to his tying his night-cap too close under his fat cheeks and chin, which caused his suffocation; but the facetious Andrew Marvel has written a poem of 100 lines, to make him a martyr of Bacchus, and die by the force of good wine. He was interred near Camden, in Westminster-Abbey; which caused Dr Fuller to say, that "if he were a biased and partial writer, yet he lieth buried near a good and true historian indeed." Soon after the restoration, his body, with those of several others, was dug up, and buried in a pit in St Margaret's church-yard; and his monument, which was erected by the appointment of Parliament, was taken down and thrown aside.

MAYER (Tobias), one of the greatest astronomers and mechanics this century has produced, was born at Mafpach, in the duchy of Wirtemberg 1723. He taught himself mathematics, and at the age of fourteen designed machines and instruments with the greatest dexterity and justness. These pursuits did not hinder him from cultivating the belles lettres. He acquired the Latin tongue, and wrote it with elegance. In 1750, the university of Gottingen chose him for their mathematical professor; and every year of his short life was thenceforward marked with some considerable discoveries in geometry and astronomy. He published several works in this way, which are all reckoned excellent; and some are inserted in the second volume of the "Memoirs of the university of Gottingen." His labours seem to have exhausted him; for he died worn out in 1762.

MAYERNE (Sir Theodore de), baron of Aulbone, was the son of Lewis de Mayerne, the celebrated author of *The general history of Spain*, and of the *Monarchie aristo-democratique*, dedicated to the states-general. He was born in 1573, and had for his god-father Theodore Beza. He studied physic at Montpellier, and was made physician in ordinary to Henry IV. who promised to do great things for him provided he would change his religion. James I. of England invited him over, and made him first physician to himself and his queen, in which office he served the whole royal family to the time of his death in

1655.

Mayhem 1655. His works were printed at London in 1702, and make a large folio, divided into two books; the first containing his *Consilia, Epistolæ, & Observationes*; the second his *Pharmacopœia varique medicamentorum formulæ*.

MAYHEM. See MAIM.

MAYNE (Jasper), an eminent English poet and divine in the 17th century, who was bred at Oxford, and entered into holy orders. While his majesty resided at Oxford, he was one of the divines appointed to preach before him. He published in 1647 a piece intitled, OXAOMAXIA, or, *The people's war examined according to the principles of reason and scripture, by Jasper Mayne*. In 1648 he was deprived of his studentship at Christ-church, and two livings he had; but was restored with the king, who made him his chaplain and archdeacon of Chichester; all which he held till he died. Dr Mayne was held in very high esteem both for his natural parts and his acquired accomplishments. He was an orthodox preacher, and a man of severe virtue and exemplary behaviour; yet of a ready and facetious wit, and a very singular turn of humour. From some stories that are related of him, he seems to have borne some degree of resemblance in his manner to the celebrated Dr Swift; but if he did not possess those very brilliant parts that distinguished the Dean, he probably was less subject to that capricious and those unaccountable whimsies which at times so greatly eclipsed the abilities of the latter. Yet there is one anecdote related of him, which, although it reflects no great honour on his memory, as it seems to carry some degree of cruelty with it, yet is it a strong mark of his resemblance to the Dean, and a proof that his propensity for drollery and joke did not quit him even in his latest moments. The story is this: The doctor had an old servant, who had lived with him some years, to whom he had bequeathed an old trunk, in which he told him he would find *something that would make him drink after his death*. The servant, full of expectation that his master, under this familiar expression, had left him somewhat that would be a reward for the assiduity of his past services, as soon as decency would permit flew to the trunk; when behold, to his great disappointment, the boasted legacy proved to be a red herring. The doctor, however, bequeathed many legacies by will to pious uses; particularly 50 pounds towards the rebuilding of St Paul's cathedral, and 200 pounds to be distributed to the poor of the parishes of Cassington and Pyrtown, near Watlington, of both which places he had been vicar. In his younger years he had an attachment to poetry; and wrote two plays, the latter of which may be seen in the tenth volume of Doddsley's collection, viz. 1. *Amorous war*, a tragedy. 2. *The city-match*, a comedy. He published a poem upon the naval victory by the duke of York over the Dutch, printed in 1665. He also translated into English from the Greek part of Lucian's Dialogues.

MAYNOOTH, or MANOOTH, a post town in the county of Kildare, and province of Leinster, in Ireland, near 12 miles from Dublin. Though not very large, it is regularly laid out, and consists of good houses. Here is a charter-school, which was opened 27th July 1759.

Vol. X. Part II.

MAYNWARING (Arthur), an eminent political writer in the beginning of the 18th century, staid several years at Oxford, and then went to Cheshire, where he lived some time with his uncle Mr Francis Cholmondeley, a very honest gentleman, but extremely averse to the government of king William III. to whom he refused the oaths. Here he prosecuted his studies in polite literature with great vigour; and coming up to London, applied to the study of the law. He was hitherto very zealous in anti-revolutional principles, and wrote several pieces in favour of king James II.; but upon being introduced to the duke of Somerset and the earls of Dorset and Burlington, began to entertain very different notions in politics. His father left him an estate of near 800 l. a-year, but so incumbered, that the interest money amounted to almost as much as the revenue. Upon the conclusion of the peace he went to Paris, where he became acquainted with Mr Boileau. After his return he was made one of the commissioners of the customs, in which post he distinguished himself by his skill and industry. He was a member of the kit-cat-club, and was looked upon as one of the chief supports of it by his pleasantry and wit. In the beginning of queen Anne's reign, the lord treasurer Godolphin engaged Mr Done to quit the office of auditor of the imposts, and made Maynwarine a present of a patent for that office worth about 2000 l. a-year in a time of business. He had a considerable share in the Medley, and was author of several other pieces. The Examiner, his antagonist in politics, allowed that he wrote with tolerable spirit, and in a masterly style. Sir Richard Steele dedicated the first volume of the Tatler to him.

MAYO, one of the Cape de Verd islands, lying in the Atlantic ocean, near 300 miles from Cape Verd in Africa, about 17 miles in circumference. The soil in general is very barren, and water scarce; however, they have some corn, yams, potatoes, and plantains, with plenty of beeves, goats, and asses. What trees there are, grow on the sides of the hills, and they have some figs and water-melons. The sea round about the island abounds with fish. The chief commodity is salt, with which many English ships are loaded in the summer-time. The principal town is Pinosa, inhabited by negroes, who speak the Portuguese language, and are stout, lully, and fleshy. They are not above 200 in number, and many of them go quite naked. W. Long, 21. 25. N. Lat. 15. 5.

MAYO, a county of Ireland, in the province of Connaught, having Sligo and the sea on the north, Roscommon on the south, Leitrim and Roscommon on the east, and the Atlantic ocean on the west. It contains 724,640 Irish plantation acres, 73 parishes, 9 baronies, and one borough; and sends four members to parliament. It gives title of earl to the family of Bourke. This county takes its name from an ancient city, built in 664; the ruins of the cathedral, and some traces of the stone walls which encompassed the city, yet remain on the plains of Mayo. It was a university, founded for the education of such of the Saxon youths as were converted to the Christian faith: it was situated a little to the south of Lough Conn; and is to this day frequently called *Mayo of the Saxons*, being celebrated for giving education to Alfred the great king of England. As this town has

Maynwaring, Mayo.

Mayor.

gone to decay, Balinrobe is reckoned the chief town. The country by the sea is mountainous; but inland has good pastures, lakes, and rivers. It is about 57 miles long, and 48 broad. Cattlebar is the assizes town.— Mayo was formerly a bishop's see, which is now united to Tuam.

MAYOR, the chief magistrate of a city or town, chosen annually out of the aldermen. The word, anciently wrote *mayr*, comes from the British *miret*, i. e. *custodire*, or from the old English *maier*, viz. *potestas*, and not from the Latin *major*. King Richard I. in 1189, changed the bailiff of London into a mayor, and from that example king John made the bailiff of King's Lynn a mayor anno 1204: Though the famous city of Norfolk obtained not this title for its chief magistrate till the seventh year of king Henry V. anno 1419; since which there are few towns of note but have had a mayor appointed for government.

Mayors of corporations are justices of peace *pro tempore*, and they are mentioned in several statutes; but no person shall bear any office of magistracy concerning the government of any town, corporation, &c. who hath not received the sacrament according to the church of England within one year before his election, and who shall not take the oaths of supremacy, &c.

If any person intrudes into the office of mayor, a *quo warranto* lies against him, upon which he shall not only be ousted, but fined. And no mayor, or person holding an annual office in a corporation for one year, is to be elected into the same office for the next; in this case, persons obstructing the choice of a successor are subject to 100 l. penalty. Where the mayor of a corporation is not chosen on the day appointed by charter, the next office in place shall the day after hold a court and elect one; and if there be a default or omission that way, the electors may be compelled to choose a mayor, by a writ of *mandamus* out of the king's bench. Mayors, or other magistrates of a corporation, who shall voluntarily absent themselves on the day of election, are liable to be imprisoned, and disqualified from holding any office in the corporation.

MAYOR'S COURTS. To the lord mayor and city of London belong several courts of judicature. The highest and most ancient is that called the *hustings*, designed to secure the laws, rights, franchises, and customs of the city. The second is a court of *request*, or of *conscience*; of which before. The third is the court of the lord mayor and aldermen, where also the sheriffs sit: to which may be added two courts of sheriffs and the court of the city orphans, whereof the lord mayor and aldermen have the custody. Also the court of common council, which is a court or assembly, wherein are made all by-laws which bind the citizens of London. It consists, like the parliament, of two houses: an upper, consisting of the lord mayor and aldermen; and a lower, of a number of common council men, chose by the several wards, as representatives of the body of the citizens. In the court of common council are made laws for the advancement of trade, and committees yearly appointed, &c. But acts made by them are to have the assent of the lord mayor and aldermen, by stat. 11 Geo. I. Also the chamberlain's

Maga

Mazarine.

court, where every thing relating to the rents and revenues of the city, as also the affairs of servants, &c. are transacted. Lastly, to the lord mayor belong the courts of coroner and of escheator; another court for the conservation of the river Thames; another of gaol-delivery, held usually eight times a year, at the Old Bailey, for the trial of criminals, whereof the lord mayor is himself the chief judge. There are other courts called *wardmotes* or meetings of the wards; and courts of halmote or assemblies of the several guilds and fraternities.

MAZA, among the Athenians, was a sort of cake made of flour boiled with water and oil, and set, as the common fare, before such as were entertained at the public expence in the common hall or *prytaneum*.

MAZAGAN, a strong place of Africa, in the kingdom of Morocco, and on the frontiers of the province of Duguela. It was fortified by the Portuguese, and besieged by the king of Morocco with 200,000 men in 1562, but to no purpose. It is situated near the sea. W. Long. 7. 45. N. Lat. 33. 5.

MAZARA, an ancient town of Sicily, and capital of a considerable valley of the same name, which is very fertile, and watered with several rivers. The town is a bishop's see, and has a good harbour; is seated on the sea coast, in E. Long. 12. 39. N. Lat. 37. 42.

MAZARINE (Julius), a famous cardinal and prime minister of France, was born at Piscina in the province of Abruzzo, in Naples, in 1602. After having finished his studies in Italy and Spain, he entered into the service of cardinal Sachetti, and became well skilled in politics, and in the interests of the princes at war in Italy; by which means he was enabled to bring affairs to an accommodation, and the peace of Queiras was shortly concluded. Cardinal Richelieu being taken with his conduct, did from thenceforward highly esteem him; as did also cardinal Antonio, and Louis XIII. who procured him a cardinal's hat in 1641. Richelieu made him one of the executors of his will; and during the minority of Louis XIV. he had the charge of affairs. At last he became the envy of the nobility, which occasioned a civil war; whereupon Mazarine was forced to retire, a price was set on his head, and his library sold. Notwithstanding he afterwards returned to the court in more glory than ever; concluded a peace with Spain, and a marriage treaty betwixt the king and the infant. This treaty of peace passes for the masterpiece of cardinal de Mazarine's politics, and procured him the French king's most intimate confidence: but at last his continual application to business threw him into a disease, of which he died at Vincennes in 1661.—Cardinal Mazarine was of a mild and affable temper. One of his greatest talents was his knowing mankind, and his being able to adapt himself, and to assume a character conformable to the circumstances of affairs. He possessed at one and the same time the bishopric of Metz, and the abbey of St Arnaud, St Clement, and St Vincent, in the same city; that of St Dennis, Clugny, and Victor, of Marseilles; of St Michael at Soissons, and a great number of others. He founded Mazarine-college at Paris, which is also called the *college of the four nations*. There has been published a collection of his letters, the most copious

Mazzuoli, copious edition of which is that of 1745, in 2 vols duodecimo.

MAZZUOLI. See PARMIGIANO.

MEAD, a wholesome, agreeable liquor, prepared of honey and water.

One of the best methods of preparing mead is as follows : Into twelve gallons of water dip the whites of six eggs ; mixing these well together, and to the mixture adding twenty pounds of honey. Let the liquor boil an hour, and when boiled add cinnamon, ginger, cloves, mace, and a rosemary. As soon as it is cold, put a spoonful of yest to it, and tun it up, keeping the vessel filled as it works ; when it has done working, stop it up close ; and, when fine, bottle it off for use.

Thorley says, that mead not inferior to the best of foreign wines may be made in the following manner : Put three pounds of the finest honey to one gallon of water, and two lemon peels to each gallon ; boil it half an hour, well scummed ; then put in, while boiling, lemon peel : work it with yest ; then put it in your vessel with the peel, to stand five or six months, and bottle it off for use. If it is to be kept for several years, put four pounds to a gallon of water.

The author of the Dictionary of Chemistry directs to choose the whitest, purest, and best-tasted honey, and to put it into a kettle with more than its weight of water : a part of this liquor must be evaporated by boiling, and the liquor scummed, till its consistence is such, that a fresh egg shall be supported on its surface without sinking more than half its thickness into the liquor ; then the liquor is to be strained, and poured through a funnel into a barrel ; this barrel, which ought to be nearly full, must be exposed to a heat as equable as possible, from 20 to 27 or 28 degrees of Mr Reaumur's thermometer, taking care that the bung-hole be slightly covered, but not closed. The phenomena of the spirituous fermentation will appear in this liquor, and will subsist during two or three months, according to the degree of heat ; after which they will diminish and cease. During this fermentation, the barrel must be filled up occasionally with more of the same kind of liquor of honey, some of which ought to be kept a part, on purpose to replace the liquor which flows out of the barrel in froth. When the fermentation ceases, and the liquor has become very vinous, the barrel is then to be put into a cellar, and well closed ; a year afterwards the mead will be fit to be put into bottles.

Mead is a liquor of very ancient use in Britain. See the article FEAST, p. 182, col. i.

MEAD (Dr Richard), a celebrated English physician, was born at Stepney near London, where his father, the Reverend Mr Matthew Mead, had been one of the two ministers of that parish ; but in 1662 was ejected for nonconformity, but continued to preach at Stepney till his death. As Mr Mead had a handsome fortune, he bestowed a liberal education upon 13 children, of whom Richard was the eleventh ; and for that purpose kept a private tutor in his house, who taught him the Latin tongue. At 16 years of age Richard was sent to Utrecht, where he studied three years under the famous Grevius ; and then choosing the profession of physic, he went to Leyden, where he attended the lectures of the famous Pitcairn

on the theory and practice of medicine, and Hermon's botanical courses. Having also spent three years in these studies, he went with his brother and two other gentlemen to visit Italy, and at Padua took his degree of doctor of philosophy and physic in 1695. Afterwards he spent some time at Naples and at Rome ; and returning home the next year, settled at Stepney, where he married, and practised physic, with a success that laid the foundation of his future greatness.

In 1703, Dr Mead having communicated to the Royal Society an analysis of Dr Bonomo's discoveries relating to the cutaneous worms that generate the itch, which they inserted in the Philosophical Transactions ; this, with his account of poisons, procured him a place in the Royal Society, of which Sir Isaac Newton was then president. The same year he was elected physician of St Thomas's hospital, and was also employed by the surgeons to read anatomical lectures in their hall, which obliged him to remove into the city. In 1707 his Paduan diploma for doctor of physic was confirmed by the university of Oxford ; and being patronized by Dr Radcliffe, on the death of that famous physician he succeeded him in his house at Bloomsbury-square, and in the greatest part of his business. In 1727 he was made physician to King George II. whom he had also served in that capacity while he was prince of Wales ; and he had afterwards the pleasure of seeing his two sons-in-law, Dr Nichols and Dr Wilmot, his coadjutors in that eminent station.

Dr Mead was not more to be admired for the qualities of the head than he was to be loved for those of his heart. Though he was himself a hearty whig, yet, uninfluenced by party-principles, he was a friend to all men of merit, by whatever denomination they might happen to be distinguished. Thus he was intimate with Garth, with Arbuthnot, and with Freind ; and long kept up a constant correspondence with the great Boerhaave, who had been his fellow-student at Leyden ; they communicated to each other their observations and projects, and never loved each other the less for being of different sentiments. In the mean time, intent as Dr Mead was on the duties of his profession, he had a greatness of mind that extended itself to all kinds of literature, which he spared neither pains nor money to promote. He caused the beautiful and splendid edition of Thuanus's history to be published in 1713, in seven volumes folio : and by his interpolation and assiduity, Mr Suttan's invention of drawing foul air from ships and other close places was carried into execution, and all the ships in his majesty's navy provided with this useful machine. Nothing pleased him more than to call hidden talents into light ; to give encouragement to the greatest projects, and to see them executed under his own eye. During almost half a century he was at the head of his business, which brought him one year above seven thousand pounds, and for several years between five and six thousand : yet clergymen, and in general all men of learning, were welcome to his advice. His library consisted of 10,000 volumes, of which his Latin, Greek, and oriental manuscripts, made no inconsiderable part. He had a gallery for his pictures and antiquities, which cost him great sums. His reputation, not only as a

Meadow. physician, but as a scholar, was so universally established, that he corresponded with all the principal literati in Europe: even the king of Naples sent to desire a complete collection of his works; and in return made him a present of the two first volumes of Signior Bajardi, which may be considered as an introduction to the collection of the antiquities of Herculaneum. At the same time that prince invited him to his palace, that he might have an opportunity of showing him those valuable monuments of antiquity; and nothing but his great age prevented his undertaking a journey so suited to his taste. No foreigner of learning ever came to London without being introduced to Dr Mead; and on these occasions his table was always open, and the magnificence of princes was united with the pleasures of philosophers. It was principally to him that the several counties of England and our colonies abroad applied for the choice of their physicians, and he was likewise consulted by foreign physicians from Russia, Prussia, Denmark, &c. He wrote, besides the above works, 1. *A Treatise on the Scurvy*. 2. *De variolis et morbillis dissertatio*. 3. *Medica sacra: sive de Morbis insignioribus, qui in Bibliis memorantur, Commentarius*. 4. *Monita et Præcepta medica*. 5. *A Discourse concerning peccilential contagion, and the methods to be used to prevent it*. The works he wrote and published in Latin were translated into English, under the doctor's inspection, by Thomas Stack, M. D. and F. R. S. This great physician, naturalist, and antiquarian, died on the 16th of February 1754.

MEADOW, in its general signification, means pasture or grass-land, annually mown for hay: but it is more particularly applied to lands that are so low as to be too moist for cattle to graze upon them in winter without spoiling the sward.

An improvement in agriculture by watering of meadows has of late come into much use, and been found of very considerable importance. In the Monthly Review for October 1788, the editors acknowledge the favour of a correspondent, who informed them, that watering of meadows was practised during the reigns of Queen Elizabeth and James I. A book was written upon the subject by one Rowland Vaughan, who seems to have been the inventor of this art, and who practised it on a very extensive plan in the Golden Valley in Herefordshire. Till this note to the Reviewers appeared, the inhabitants of a village called South-Cerney in Gloucestershire had assumed the honour of the invention to themselves, as we are informed in a treatise upon the subject by the reverend Mr Wright curate of the place. According to a received tradition in that village, watering of meadows has been practised there for about a century, and was introduced by one *Wellavise*, a wealthy farmer in South-Cerney. His first experiment was by cutting a large ditch in the middle of his ground, from which he threw the water over some parts, and allowed it to stagnate in others: but finding this not to answer his expectations, he improved his method by cutting drains and filling up the hollows; and thus he succeeded so well, that his neighbours, who at first had called him a madman, soon changed their opinion, and began to imitate his example.

The advantages which attend the watering of meadows are many and great; not only as excellent crops

of grass are thus raised, but as they appear so early, Meadow. that they are of infinite service to the farmers for food to their cattle in the spring before the natural grass rises. By watering we have plenty of grass in the beginning of March, and even earlier when the season is mild. The good effects of this kind of grass upon all sorts of cattle are likewise astonishing, especially upon such as have been hardly wintered; and Mr Wright informs us, that the farmers in his neighbourhood, by means of watering their lands, are enabled to begin the making of cheese at least a month sooner than their neighbours who have not the same advantage. Grass raised by watering is found to be admirable for the nurture of lambs; not only those designed for fattening, but such as are to be kept for store: For if lambs when very young are stopped and stinted in their growth, they not only become contracted for life themselves, but in some measure communicate the same diminutive size to their young. The best remedy for preventing this evil is the spring feed from watered meadows; and Mr Wright is of opinion, that if the young of all kinds of farmer's stock were immediately encouraged by plenty of food, and kept continually in a growing state, there would in a few years be a notable change both in the size and shape of cattle in general. Such indeed is the forwardness of grass from watered meadows, that the feed between March and May is worth a guinea per acre; and in June an acre will yield two tons of hay, and the after-math is always worth twenty shillings; and nearly the same quantity is constantly obtained whether the summer be dry or wet. In dry summers also, such farmers as water their meadows have an opportunity of selling their hay almost at any price to their neighbours.

Land treated in this manner is continually improving in quality, even though it be mown every year: the herbage, if coarse at first, becomes finer; the soil, if swampy, becomes found; the depth of its mould is augmented, and its quality meliorated every year. To these advantages (says Mr Boswell in his treatise upon this subject) another may be addressed to the gentleman who wishes to improve his estate, and whose benevolent heart prompts him to extend a charitable hand to the relief of the indolent poor, and not to idleness and vice: almost the whole of the expence in this mode of cultivation is the actual manual labour of a class of people who have no genius to employ their bodily strength otherwise for their own support and that of their families; consequently, when viewed in this light, the expence can be but comparatively small, the improvement great and valuable.

As a proof of the above doctrine, Mr Wright adduces an instance of one year's produce of a meadow in his neighbourhood. It had been watered longer of than the eldest person in the neighbourhood could remember; but was by no means the best meadow upon the stream, nor was the preceding winter favourable for watering. It contains six acres and an half. The spring-feed was let for seven guineas, and supported near 200 sheep from the 1st of March till the beginning of May: the hay being sold for 30 guineas, and the after-math for six. Another and still more remarkable proof of the efficacy of watering, is, that two of the most skillful watermen of that place were sent to lay out a meadow of seven acres, the whole crop of which was that year sold for

Meadow. two pounds. Though it was thought by many impossible to throw the water over it, yet the skill of the workmen soon overcame all difficulties; and ever since that time the meadow has been let at the rent of three pounds per acre. From manifold experience, our author informs us, that the people in that part of the country are so much attached to the practice of watering, that they never suffer the smallest spring or rivulet to be unemployed. Even those temporary floods occasioned by sudden showers are received into proper ditches, and spread equally over the lands until its fertilizing property be totally exhausted. "Necessity (says he) indeed compels us to make the most of every drop; for we have near 300 acres in this parish, that must all, if possible, be watered; and the stream that affords the water seldom exceeds five yards in breadth and one in depth: therefore we may say, that a scarcity of water is almost as much dreaded by us as by the celebrated inhabitants of the banks of the Nile."

5 The practice of watering ought to be more generally extended. Considering the great advantages to be derived from the practice of watering meadows, and the many undoubted testimonies in its favour, Mr Wright expresses his surprise that it has not come into more general use, as there is not a stream of water upon which a mill can be erected but what may be made subservient to the enriching of some land, perhaps to a great quantity. "I am confident (says he), that there are in each county of England and Wales 2000 acres upon an average which might be thus treated, and every acre increased at least one pound in annual value. The general adoption therefore of watering is capable of being made a national advantage of more than 100,000*l.* per annum, besides the great improvement of other land arising from the produce of the meadows and the employment of the industrious poor. Such an improvement, one would think, is not unworthy of public notice; but if I had doubled the sum, I believe I should not have exceeded the truth, though I might have gone beyond the bounds of general credibility. In this one parish where I reside there are about 300 acres now watered; and it may be easily proved that the proprietors of the land reap from thence 1000*l.* yearly profit."

In Mr Boswell's treatise upon this subject, published in 1790, the author complains of the neglect of the practice of improving the wet, boggy, and rushy lands, which lie at the banks of rivers, and might be meliorated at a very small expence, when much larger sums are expended in the improvement of barren uplands and large tracts of heath in various parts of the kingdom; and he complains likewise of the little information that is to be had in books concerning the method of performing this operation. The only author from whom he acknowledges to have received any information is Blyth; and even his method of watering is very different from that practised in modern times; for which reason he proposes to furnish an original treatise upon the subject; and of this we shall now give the substance.

6 The first thing to be considered is, what lands are capable of being watered. These, according to Mr Boswell, are all such as lie low, near the banks of rivulets and springs, especially where the water-course is higher than the lands, and kept within its bounds by banks. If the rivulet has a quick descent, the im-

provement by watering will be very great, and the expences moderate. On level lands the water runs but slowly, which is also the case with large rivers; and therefore only a small quantity of ground can be overflowed by them in comparison of what can be done in other cases: but the water of large rivers is generally possessed of more fertilizing properties than that of rivulets. In many cases, however, the rivers are navigable, or have mills upon them; both of which are strong objections to the perfect improvement of lands adjacent to them. From these considerations, our author concludes, that the watering of lands may be performed in the best and least expensive manner by small rivulets and springs.

There are three kinds of soils commonly found near the banks of rivers and rivulets, the melioration of which may be attempted by watering. 1. A gravelly or found warm firm soil, or a mixture of the two together. This receives an almost instantaneous improvement; and the faster the water runs over it the better. 2. Boggy, miry, and rushy soils, which are always found by the banks of rivers where the land is nearly level. These also are greatly improved by watering; perhaps equally so with those already described, if we compare the value of both in their unimproved state, this kind of ground being scarce worth any thing in its unimproved state. By proper watering, however, it may be made to produce large crops of hay, by which horned cattle may be kept through the winter and greatly forwarded; though, in its uncultivated state, it would scarce produce any thing to maintain stock in the winter, and very little even in summer. Much more skill, as well as expence, however, is requisite to bring this kind of land into culture than the former. 3. The soils most difficult to be improved are strong, wet, and clay soils; and this difficulty is occasioned both by their being commonly on a dead level, which will not admit of the water running over them; and by their tenacity, which will not admit of draining. Even when the utmost care is taken, unless a strong body of water is thrown over them, and that from a river the water of which has a very fertilizing property, little advantage will be gained; but wherever such advantages can be had in the winter, and a warm spring succeeds, these lands will produce very large crops of grass.

7 The advantage of using springs and rivulets for watering instead of large rivers is, that the expence of raising waters across them will not be great; nor are they liable to the other objections which attend the use of large rivers. When they run through a cultivated country also, the land floods occasioned by violent rains frequently bring with them such quantities of manure as contribute greatly to fertilize the lands, and which are totally lost where the practice of watering is not in use.

Springs may be useful to the coarse lands that lie near them, provided the water can be had in sufficient quantity to overflow the lands. "By springs (says our author), are not here meant such as rise out of poor heath or boggy lands (for the water issuing from them is generally so small in quantity, and always so very lean and hungry in quality, that little if any advantage can be derived from it); but rather the head of rivulets and brooks rising out of a chalky and gravelly

Meadow.

5 The practice of watering ought to be more generally extended.

6 Land capable of being watered.

7 Watering instead of large rivers is, that the expence of raising waters across them will not be great; nor are they liable to the other objections which attend the use of large rivers.

Meadow. gravelly found firm soil, in a cultivated country. These are invaluable; and every possible advantage should be taken to improve the ground near them. The author knows a considerable tract of meadow-land under this predicament; and one meadow in particular that is watered by springs issuing immediately out of such a soil, without any advantage from great towns, &c. being situated but a small distance below the head of the rivulet, and the rivulet itself is fed all the way by springs rising out of its bed as clear as crystal. The soil of the meadow is a good loam some inches deep, upon a fine springy gravel. Whether it is from the heat of the springs, or whether the friction by the water running over the soil raises a certain degree of warmth favourable to vegetation, or from whatever cause it arises, the fecundity of this water is beyond conception; for when the meadow has been properly watered and well drained, in a warm spring, the grass has been frequently cut for hay within five weeks from the time the stock was taken out of it, having eat it bare to the earth: almost every year it is cut in six weeks, and the produce from one to three waggon loads to an acre. In land thus situated, in the mornings and evenings in the months of April, May, and June, the whole meadow will appear like a large furnace; so considerable is the steam or vapour which arises from the warmth of the springs acted upon by the sun-beams: and although the water is so exceeding clear, yet upon its being thrown over the land only a few days in warm weather, by dribbling through the grass, so thick a scum will arise and adhere to the blades of the grass, as will be equal to a considerable quantity of manure spread over the land, and (it may be presumed from the good effects) still more enriching.

"It is inconceivable what 24 hours water properly conveyed over the lands will do in such a season: a beautiful verdure will arise in a few days where a parched rusty soil could only be seen; and one acre will then be found to maintain more stock than ten could do before."

8
Explanation of the terms used in water-works.

Mr Boswell next proceeds to an explanation of the terms used in this art; of the instruments necessary to perform it; and of the principles on which it is founded. The terms used are:

1. A **WARE.** This is an erection across a brook, rivulet, or river, frequently constructed of timber, but more commonly of bricks or stones and timber, with openings to let the water pass, from two to ten in number according to the breadth of the stream; the height being always equal to the depth of the stream compared with the adjacent land. The use of this is occasionally to stop the current, and to turn it aside into the adjacent lands.

2. A **SLUICE** is constructed in the same manner as a ware; only that it has but a single passage for the water, and is put across small streams for the same purposes as a ware.

3. A **TRUNK** is designed to answer the same purposes as a sluice; but being placed across such streams as either cattle or teams are to pass over, or where it is necessary to carry a small stream at right angles to a large one to water some lands lower down, is for these reasons made of timber, and is of a square figure.

The length and breadth are various as circumstances determine.

4. A **CARRIAGE** is made of timber or of brick. If of timber, oak is the best; if of brick, an arch ought to be thrown over the stream that runs under it, and the sides bricked up: But when made of timber, which is the most common material, it is constructed with a bottom and sides as wide and high as the main in which it lies. It must be made very strong, close, and well-jointed. Its use is to convey the water in one main over another, which runs at right angles to it; the depth and breadth are the same with those of the main to which it belongs; and the length is determined by that which it crosses. The carriage is the most expensive instrument belonging to watering.

5. A **DRAIN-SLUICE, or Drain-Trunk**, is always placed in the lower part of some main, as near to the head as a drain can be found; that is, situated low enough to draw the main, &c. It is made of timber, of a square figure like a trunk, only much smaller. It is placed with its mouth at the bottom of the main, and let down into the bank; and from its other end a drain is cut to communicate with some trench drain that is nearest. The dimensions are various, and determined by circumstances. The use of it is, when the water is turned some other way, to convey the leaking water that oozes through the hatches, &c. into the drain, that otherwise would run down into the tails of those trenches which lie lowest, and there poach and rot the ground, and probably contribute not a little to the making it more unfound for sheep. This operation is of the utmost consequence in watering; for if the water be not thoroughly drained off the land, the soil is rotted; and when the hay comes to be removed, the wheels of the carriages sink, the horses are mired, and the whole load sometimes sticks fast for hours together. On the other hand, when the drain-trunks are properly placed, the ground becomes firm and dry, and the hay is speedily and easily removed.

7. **HATCHES** are best made of oak, elm, or deal; the use of them is to fit the openings of wares, trunks, or sluices; and to keep back the water when necessary, from passing one way, to turn it another. They ought to be made to fit as close as possible. When hatches belong to wares that are erected across large streams, or where the streams swell quickly with heavy rains, when the hatches are in their places to water the meadows; they are sometimes made so, that a foot or more of the upper part can be taken off, so that vent may be given to the superfluous water, and yet enough retained for the purpose of watering the meadows. In this case, they are called *flood-hatches*; but Mr Boswell entirely disapproves of this construction, and recommends them to be made entire, though they should be ever so heavy, and require the assistance of a lever to raise them up. For when the water is very high, and the hatches are suddenly drawn up, the water falls with great force upon the bed of the ware, and in time greatly injures it: but when the whole hatch is drawn up a little way, the water runs off at the bottom, and does no injury.

8. A **HEAD-MAIN**, is a ditch drawn from the river, rivulet, &c. to convey the water out of its usual current,

Meadow. current, to water the lands laid out for that purpose, by means of lesser mains and trenches. The head-main is made of various dimensions according to the quantity of land to be watered, the length or descent of it, &c. Smaller mains are frequently taken out of the head one; and the only difference is in point of size, the secondary mains being much smaller than the other. They are generally cut at right angles, or nearly so with the other, though not invariably. The use of the the mains, whether great or small, is to feed the trenches with water, which branch out into all parts of the meadow, and convey the water to float the land. By some, these smaller mains are improperly called *Carriages*.

9. A **TRENCH** is a small ditch made to convey the water out of the mains for the immediate purpose of watering the land. It ought always to be drawn in a straight line from angle to angle, with as few turnings as possible. It is never deep, but the width is in proportion to the length it runs, and the breadth of the plane between that and the trench-drain. The breadth tapers gradually to the lower end.

10. A **TRENCH-DRAIN** is always cut parallel to the trench, and as deep as the tail-drain water will admit, when necessary. It ought always, if possible, to be cut down to a stratum of sand, gravel, or clay. If into the latter, a spade's depth into it will be of great advantage. The use of it is to carry away the water immediately after it has run over the panes from the trench. It need not be drawn up to the head of the land by five, six, or more yards, according to the nature of the soil. Its form is directly the reverse of the trench; being narrower at the head, and growing gradually wider and wider until it empties itself into the tail-drain.

11. The **TAIL-DRAIN** is designed as a receptacle for all the water that flows out of the other drains, which are so situated that they cannot empty themselves into the river. It should run, therefore, nearly at right angles with the trenches, though generally it is thought most eligible to draw it in the lowest part of the ground, and to use it to convey the water out of the meadows at the place where there is the greatest descent; which is usually in one of the fence-ditches; and hence a fence-ditch is usually made use of instead of a tail-drain, and answers the double purpose of fencing a meadow and draining it at the same time.

12. A **PANE** of ground, is that part of the meadow which lies between the trench and the trench-drain; and in which the grass grows for hay. It is watered by the trenches, and drained by the trench-drains; whence there is a pane on each side of every trench.

13. A **WAY-PANE** is that part of the ground which lies in a properly watered meadow, on the side of the main where no trenches are taken out, but is watered the whole length of the main over its banks. A drain for carrying off the water from this pane runs parallel to the main. The use is to convey the hay out of the meadows, instead of the teams having to cross all the trenches.

14. A **BEND** is made in various parts of those trenches which have a quick descent, to obstruct the water. It is made, by leaving a narrow strip of green sward across the trench where the bend is intended to

be left; cutting occasionally a piece of the shape of a wedge out of the middle of it. The use is to check the water, and force it over the trench into the panes; which, were it not for these bends, would run rapidly on in the trench, and not flow over the land as it passes along. The great art in watering consists in giving to each part of the pane an equal proportion of water.

15. A **GUTTER** is a small groove cut out from the tails of these trenches where the panes run longer at one corner than the other. The use is to carry the water to the extreme point of the pane. Those panes which are intersected by the trench and tail-drains, meeting in an obtuse angle, require the assistance of gutters to convey the water to the longest side. They are likewise useful, when the land has not been so well levelled, but some parts of the panes lie higher than they ought: in which case, a gutter is drawn from the trench over that high ground, which otherwise would not be overflowed. Without this precaution, unless the flats be filled up (which ought always to be done when materials can be had to do it) the water will not rise upon it; and after the watering season is past, those places would appear rusty and brown, while the rest is covered with beautiful verdure. Our author, however, is of opinion, that this method of treating water-meadows ought never to be followed; but that every inequality in water-meadows should either be levelled or filled up. Hence the waterman's skill is shown in bringing the water over those places to which it could not naturally rise, and in carrying it off from those where it would naturally stagnate.

16. A **CATCH-DRAIN** is sometimes made use of when water is scarce. When a meadow is pretty long, and has a quick descent, and the water runs quickly down the drains, it is customary to stop one or more of them at a proper place, till the water flowing thither rises so high as to strike back either into the tail-drains so as to stagnate upon the sides of the panes, or till it flows over the banks of the drains and waters the grounds below, or upon each side. It is then to be conveyed over the land in such quantity as is thought proper, either by a small main, out of which trenches are to be cut with their proper drains, or by trenches taken properly out of it. In case of a stagnation, the design will not succeed; and it will then be necessary to cut a passage to let the stagnating water run off. Even when the method succeeds best, Mr Boswell is of opinion, that it is not by any means eligible; the water having been so lately strained over the ground, that it is supplied by the water-men not to be endowed with such fertilizing qualities as at first; whence nothing but absolute necessity can justify the practice.

17. A **POND** is any quantity of water stagnating upon the ground, or in the tail-drain, trench-drains, &c. so as to annoy the ground near them. It is occasioned sometimes by the flats not having been properly filled up; at others, when the ware not being close shut, in order to water some grounds higher up, the water is thereby thrown back upon the ground adjacent.

18. A **TURN** of water signifies as much ground as can be watered at once. It is done by shutting down the

Meadow. the hatches in all those wares where the water is intended to be kept out, and opening those that are to let the water through them. The quantity of land to be watered at once must vary according to circumstances; but Mr Boswell lays down one general rule in this case, viz. that no more land ought to be kept under water at one time than the stream can supply regularly with a sufficient quantity of water; and if this can be procured, water as much ground as possible.

19. The **HEAD** of the meadow, is that part of it into which the river, main, &c. first enter.

20. The **TAIL** is that part out of which the river, &c. last passes.

21. The **UPPER SIDE** of a main or trench, is that side which (when the main or trench is drawn at right angles, or nearly so, with the river) fronts the part where the river entered. The lower side is the opposite.

22. The **UPPER PANE** in a meadow, is that which lies on the upper side of the main or trench that is drawn at right angles with the river: where the river runs north and south, it enters in the former direction, and runs out in the southern, the main and trenches running east and west. Then all those panes which lie on the north side of the mains are called *upper panes*; and those on the south side the *lower panes*. But when the mains, trenches, &c. run parallel to the river, there is no distinction of panes into upper and lower.

The instruments used in watering meadows are:

1. A **Water-Level**. The use of this is to take the level of the land at a distance, and compare it with that of the river, in order to know whether the ground can be overflowed by it or not. This instrument, however, is useful only in large undertakings; for such as are on a smaller scale, the workmen dispense with it in the following manner: In drawing a main, they begin at the head, and work deep enough to have the water follow them. In drawing a tail-drain, they begin at the lower end of it and work upwards, to let the tail-water come after them. By this method we obtain the most exact level.

2. The **Line, Reel, and Breast-Plough**, are absolutely necessary. The line ought to be larger and stronger than that used by gardeners.

3. **Spades**. Those used in watering meadows are made of a particular form, on purpose for the work; having a stem considerably more crooked than those of any other kind. The bit is iron, about a foot wide in the middle, and terminating in a point: a thick ridge runs perpendicularly down the middle, from the stem almost to the point. The edges on both sides are drawn very thin, and being frequently ground and whetted, the whole soon becomes narrow; after which the spades are used for trenches and drains; new ones being procured for other purposes. The stems being made crooked, the workmen standing in the trench or drain are enabled to make the bottoms quite smooth and even.

4. **Wheel and Hand barrows**. The former are used for removing the clods to the flat places, and are quite open, without any sides or hinder part. The latter are of service where the ground is too soft to admit the use of wheel-barrows, and when clods are to be re-

moved during the time that the meadow is under **Meadow.** water.

5. **Three-wheeled carts** are necessary when large quantities of earth are to be removed; particularly when they are to be carried to some distance.

6. Short and narrow **Scythes** are made use of to mow the weeds and grass, when the water is running in the trenches, drains, and mains.

7. **Forks**, and long **Crooks** with four or five tines, are used for pulling out the roots of sedge, rushes, reeds, &c. which grow in the large mains and drains. The crooks should be made light, and have long stems to reach wherever the water is so deep that the workmen cannot work in it.

8. Strong **Water-boots**, the tops of which will draw up half the length of the thigh, are indispensably necessary. They must also be large enough to admit a quantity of hay to be stuffed down all round the legs, and be kept well tallowed to resist the running water for many hours together.

The principles on which the practice of watering meadows depend are few and easy.

1. Water will always rise to the level of the receptacle out of which it is originally brought.

2. There is in all streams a descent greater or smaller; the quantity of which is in some measure shown by the running of the stream itself. If it runs smooth and slow, the descent is small; but if rapidly and with noise, the descent is considerable.

3. Hence if a main be taken out of the river high enough up the stream, water may be brought from that river to flow over the land by the side of the river, to a certain distance below the head of the main, although the river from whence it is taken should, opposite to that very place, be greatly under it.

4. Water, sunk under a carriage which conveys another stream at right angles over it, one, two, or more feet below its own bed, will, when it has passed the carriage, rise again to the level it had before.

5. Water conveyed upon any land, and there left stagnant for any length of time, does it an injury; destroying the good herbage, and filling the place with rushes, flags, and other weeds.

6. Hence it is absolutely necessary, before the work is undertaken, to be certain that the water can be thoroughly drained off.

In Mr Wright's treatise upon this subject, the author considers a solution of the three following questions as a necessary preliminary to the operation of watering. 1. Whether the stream of water will admit of a temporary dam or ware across it? 2. Can the farmer raise the water by this means a few inches above its level, without injuring his neighbour's land? 3. Can the water be drawn off from the meadow as quick as it is brought on?—If a satisfactory answer can be given to all these questions, he directs to proceed in the following manner.

Having taken the level of the ground, and compared it with the river, as directed by Mr Boswell, cut a deep wide ditch as near the dam as possible, and by it convey the water directly to the highest part of the meadow; keeping the sides or banks of the ditch of an equal height, and about three inches higher than the general surface of the meadow. Where the mea-

Meadow. **dow** is large, and has an uneven surface, it will sometimes be necessary to have three works in different directions, each five feet wide, if the meadow contains 15 acres; and if the highest part be farthest from the stream. A ditch of 10 feet wide and three deep will commonly water 10 acres of land. When there are three works in a meadow, and flood-hatches at the mouth of each, when the water is not sufficient to cover the whole completely at once, it may be watered at three different times, by taking out one of the hatches, and keeping the other two in. In this case, when the water has run over one division of the land for 10 days, it may then be taken off that and tumbled over to another, by taking up another hatch and letting down the former; by which means the three divisions will have a proper share of the water alternately, and each reap equal benefit. The bottom of the first work ought to be as deep as the bottom of the river, when the fall in the meadow will admit of it; for the deeper the water is drawn, the more mud it carries along with it. From the works, cut, at right angles, smaller ditches or troughs, having a breadth proportioned to the distance to which some part of the water is to be carried, their distance from each other being about 12 yards. A trough two feet wide and one foot deep, will water a surface 12 yards wide and 40 feet long. In each trough as well as ditch place frequent stops and obstructions, especially when the water is rapid, to keep it high enough to flow through the notches or over the sills. Each ditch and trough is gradually contracted in width, as the quantity of water constantly decreases the farther they proceed. Between every two troughs, and at an equal distance from both, cut a drain as deep as you please parallel to them, and wide enough to receive all the water that runs over the adjacent lands, and to carry it off into the master-drain with such rapidity as to keep the whole sheet of water in constant motion; and if possible, not to suffer a drop to stagnate upon the whole meadow. "For a stagnation, says he, (though it is recommended by a Mr D. Young for the improvement of arable land), is what we never admit in our system of watering; for we find that it rots the turf, soaks and starves the land, and produces nothing but coarse grass and aquatic weeds.

"When a meadow lies cold, flat, and swampy, the width of the bed, or the distance between the trough and drain, ought to be very small, never exceeding six yards: indeed, in this case, you can scarcely cut your land too much, provided the water be plentiful; for the more you cut, the more water you require. The fall of the bed in every meadow should be half an inch in a foot: less will do, but more is desirable; for when the draught is quick, the herbage is always fine and sweet. The water ought never to flow more than two inches deep, nor less than one inch, except in the warm months."

Mr Wright proceeds now to answer some objections made by the Reviewers in their account of the first edition of his work. 1. That the Gloucestershire farmers use more water for their lands than is necessary. To this it is answered, That where water is plentiful, they find it advantageous to use even more water than he recommends; and when water is scarce, they choose rather to water only one half, or even a smaller portion of a meadow at a time, and to give that a plentiful covering, than to give a scanty one to the whole. 2. The Reviewers likewise recommend a repeated use of the same water upon different and lower parts of the same meadow, or to make each drain serve as a trough to the bed which is below it. But tho' this method is in some degree recommended by the celebrated Mr Bakewell, and taught by a systematic waterer in Staffordshire, he entirely disapproves of it; excepting where the great declivity of the land will not admit of any other plan. "This cannot (says he) be a proper mode of watering grass-land in the winter-time; for it can be of no service to the lowest parts of the meadow, unless as a wetting in spring or summer. The first or highest part of a meadow laid out according to this plan will indeed be much improved; the second may reap some benefit; but the third, which receives the exhausted thin cold water, will produce a very unprofitable crop. Our farmers never choose more than a second use in the same meadow, and that very seldom; they call even the second running by the significant name of *small-beer*; which, they say, may possibly satisfy thirst, but can give very little life or strength to land (A). It is a much better method to have a meadow laid out so as to be watered at several

Meadow.

¹¹ Objections to his method answered.

¹² A repeated use of the same water is not eligible.

4 U

veral

(A) As by the concurrence of Mr Boswell with this author, and likewise by the agreement of so many practical farmers, it seems established as a fact, that water does really lose its fertilizing properties by running over grass, it may not here be amiss to explain the principle on which it does so.

Under the article AGRICULTURE, we have shown at some length, that the true food of plants is the parts of animal and vegetable substances dissolved and volatilized by putrefaction, in such a manner that they can be absorbed by the vessels of other plants, and thus become part of their substance. There are two ways in which these effluvia may be dissolved, viz. in air and in water; of consequence, air and water are the two media by which the food of plants is applied to them, and by means of which they are augmented in bulk. From the analysis of these two elements, it is known that both of them, at least in their ordinary state, contain a great quantity of volatilized earthy matter, which sometimes strikes our senses very forcibly when first emitted by putrefying bodies; but on being thoroughly dissolved by the atmosphere, it totally eludes them, and becomes the PHLOGISTON concerning which such violent disputes have arisen. This fine volatilized matter is absorbed from the atmosphere by the leaves of the plants, and from the water by their roots. Hence both elements, when loaded with vapours of this kind, are more favourable to vegetation than when in their pure state. Thus plants will thrive very well in putrid air, while they languish and die in the pure dephlogisticated kind. Just so it is with the element of water. When this is loaded with a great quantity of putrid matter, it readily parts with it not only to the roots of plants, but to the atmosphere also; whence such vegetables as it

has

Meadow.

veral times, and to be at the expence of several small flood-hatches, than to water the whole of it at once by means of catch-drains.

" Sometimes it is necessary, in a large meadow, to convey the water that has been used under the works and troughs; and then the water above is supported by means of boards and planks, which we call a *carry-bridge*. Sometimes, the better to regulate the course of the water on the surface, especially in the spring, narrow trenches are dug, and the mould laid by the side of them, in order to be restored to its former place when the watering is finished. The earth and mud thrown out in cleansing and paring the ditches should be carried to fill up the low hollow parts of the meadow, and be trodden down with an even surface; which will easily be done when the water is on, the waterman being always provided with a strong pair of water-proof boots. If the mould thus used has upon it a turf that is tolerably fine, place it uppermost; but if it is sedgey and coarse, turn it under, and the water if it runs quick will soon produce a fine herbage upon it.

" The grounds that are watered in the easiest and most effectual manner, are such as have been ploughed and ridged up in lands about twelve yards wide. Here the water is easily carried along the ridge by means of a small ditch or trough cut along its summit, and then, by means of the flaps in it, is made to run down the sides or beds into the furrows, by which it is carried into the master drain, which empties itself into the river. Every meadow, before it is well watered, must be brought into a form something like a field that has been thus left by the plough in a ridged state. Each side of the ridge should be as nearly as possible an exact inclined plane, that the water may flow over it as equally as may be." Mr Wright does not, like Mr. Boswell, disapprove of the use of flood-hatches; he only gives the following hint, viz. that their basis should be deep and firmly fixed, well secured with stone and clay, that it be not blown up. The following directions are given for each month of watering:

73
Of cleaning
and repair-
ing the
works.

74
Thick and
muddy wa-
ter to be u-
sed when it
can be
done.

In the beginning of November, all the ditches, troughs, and drains, are to be thoroughly cleaned by the spade and breast-plough, from weeds, grass, and mud; and well repaired, if they have received any injury from cattle. After a shower, when the water is thick and muddy, turn over the meadow as much water as you can without injuring the banks of the works, especially if the land be poor; as in this month, according to our author, the water contains many more fertilizing particles, which he calls *salts* and *richness*, than later in the winter. In defence of this position, of which it seems the Monthly Reviewers have doubted, our author urges, that though he is not able to prove it by any chemical analysis, yet it seems evident,

that " after the first washing of farm yards, various Meadow. flasks, ditches, and the surface of all the adjoining fields, which have lain dry for some time, the common stream should then contain much more fatness than when the same premises have been repeatedly washed." This is confirmed by the experience of the Gloucestershire farmers; who, if they can at this season of the year procure plenty of muddy water to overflow their grounds for one week, look upon it to be equally valuable with what is procured during all the rest of the winter. In support of this, he quotes the following words of Mr Forbes, in a treatise on watering: " The water should be let in upon the meadow in November, when the first great rains make it muddy, for then it is full of a rich sediment, brought down from the lands of the country through which it runs, and is washed into it by the rain; and as the sediment brought by the first floods is the richest, the carriages and drains of the meadow should all be scoured clean and in order, before these floods come."

" In opposition (adds Mr Wright) to the opinion of practical waterers, that the muddiness of the water is of little consequence. I hesitate not to affirm, that the mud is of as much consequence in winter-watering, as dung is in the improvement of a poor upland field. For each meadow in this neighbourhood is fruitful in proportion to the quantity of mud that it collects from the water. And, indeed, what can be conceived more enriching than the abundant particles of putrid matter which float in the water, and are distributed over the surface of the land, and applied home to the roots of the grass. It is true, that any the most simple water thrown over a meadow in proper quantity, and not suffered to stagnate, will shelter it in winter, and in the warmth of spring will force a crop; but this unusual force must exhaust the strength of the land, which will require an annual supply of manure in substance, or, in a course of years, the soil will be impaired rather than improved. The meadows in this county, which lie next below a market-town or village are invariably the best; and those which receive the water after it has been two or three times used, reap proportionably less benefit from it: For every meadow that is well laid out, and has any quantity of grass upon its surface, will act as a fine sieve upon the water, which, though it flow in ever so muddy, will be returned back to the stream as clear as it came from the fountain. This circumstance, when there is a range of meadows to be watered, the property of different persons, when water is scarce, creates vehement contentions and struggles for the first use of it. The proprietors are therefore compelled to agree among themselves, either to have the first use alternately, or for the higher meadows to dam up, and use only one half or a less portion of the river. Our farmers

know

has access to, arrive at the utmost luxuriance of growth. If the water is more pure, still they will thrive very well; but the luxuriance of vegetation is less than in the former case. At last, however, when the water has parted with a certain quantity of phlogistic matter, the process of vegetation is incapable of separating any more; and therefore such water, though applied to the roots of vegetables, cannot communicate to them any remarkable increase. Nay, it is by no means improbable, that after water has arrived at this state, it will, instead of giving any fresh nourishment to the plants, again deprive them of the nourishment which they have already received; and this is probably what Mr Boswell means, when, in the passage formerly quoted, he calls the water *hungry*.

Meadow. know the mud to be of so much consequence in watering, that whenever they find it collected at the bottom of the river or the ditches, they hire men whole days to disturb and raise it with rakes made for the purpose, that it may be carried down by the water, and spread upon their meadows. One meadow in South Cerney, I think, is an incontestible proof of the consequence of muddy water. It is watered by a branch of the common stream that runs for about half a mile down a public road. This water, by the mud on the road being continually disturbed by carriages and the feet of cattle, becomes very thick, and when it enters the meadow is almost as white as milk. This field, which consists of seven acres, was a few years ago let for 10 s. an acre, but is already become the richest land in the parish, and has produced at one crop eighteen loads of hay, and each load more than 25 hundred weight."

Instance of the good effects of muddy water. 16 Mr Wimpey's opinion upon the subject. In further confirmation of what our author asserts, he quotes, from the Annals of Agriculture, the following words of Mr Wimpey: "As to the sorts of water, little is to be found, I believe, which does not encourage and promote vegetation, even the most simple, elementary, and uncompounded fluid: heat and moisture, as well as air, are the *fine qua non* of vegetation as well as animal life. Different plants require different proportions of each to live and flourish; but some of each is absolutely necessary to all. However, experience as well as reason universally shows, that the more turbid, feculent, and replete with putrescent matter the water is, the more rich and fertilizing it proves. Hasty and impetuous rains, of continuance sufficient to produce a flood, not only dissolve the salts, but wash the manure in substance off the circumjacent land into the rapid current. Such turbid water is both meat and drink to the land; and, by the unctuous sediment and mud it deposits, the soil is amazingly improved and enriched. The virtue of water from a spring, if at all superior to pure elementary water, is derived from the several strata or beds of earth it passes through, that, according to the nature of such strata, it may be friendly or otherwise to vegetation. If it passes through chalk, marble, fossil shells, or any thing of a calcareous nature, it would in moist soils promote the growth of plants; but if through metallic ores, or earth impregnated with the vitriolic acid, it would render the land unfertile, if not wholly barren. In general the water that has run far is superior to that which immediately flows from the spring, and more especially that which is feculent and muddy, consisting chiefly of putrid animal substances washed down the stream."

Confirmed by Mr Forbes. 17 To the same purpose also says Mr Forbes: "There is great difference in the quality of water, arising from the particles of different kinds of matter mixed with them. Those rivers that have a long course through good land are full of fine particles, that are highly fertilizing to such meadows as are usually overflowed by them; and this chiefly in floods, when the water is fullest of a rich sediment: for when the water is clear, though it may be raised by art high enough to overflow the adjoining lands, and be of some service to them, the improvement thus made is far short of what is obtained from the same water when it is thick and muddy."

Mr Boswell, though quoted by Mr Wright as an advocate for the doctrine just now laid down, seems, in one part of his work at least, to be of a contrary opinion. This is in the 14th chapter of his book, where he remarks upon another publication on the same subject, the name of which he does not mention: "In page 4th of that pamphlet (says Mr Boswell), the writer informs us, 'if the water used be always pure and simple, the effect will by no means be equal to the above; that is, of a stream that is sometimes thick and muddy. We have a striking instance of this in two of our meadows, which are watered immediately from springs that arise in the grounds themselves. Their crops are early and plentiful, but not of a good quality, and the land remains unimproved after many years watering.'

"The writer of this treatise (Mr Boswell), in a former edition, had asserted, and in this repeated, the contrary effects from a stream very near the spring-head, as clear as crystal.

"The gentleman (Mr Beverly of Keld) whom that writer mentions in his preface, made a short visit last spring into Dorsetshire, to satisfy himself of the fact. The editor had the pleasure to show him the stream alluded to, which he traced almost to the fountain-head. It was perfectly clear, and the water was then immediately conveyed out of the stream upon the lands adjoining, some of which it was then running over; others it had been upon, and the verdure was then appearing. The gentleman expressed himself perfectly satisfied with the fact. To him the editor wishes to refer, &c. Mr George Culley of Fenton near Wooler in Northumberland, with a truly noble and public spirit that does him great honour as a friend to his country, sent a very sensible young man from thence into Dorsetshire, to learn the art of watering meadows, and to work the whole season in those meadows under different watermen. This man was often over those meadows, and worked in some just below that were watered by the same stream. Might the editor presume to offer his opinion upon this seeming contradiction, it is very probable that the soils, both the upper and under strata, are very different, as well as those through which the different springs run."

From this passage, the latter part of which is not very intelligible, we might conclude that Mr Boswell prefers clear to muddy water for overflowing meadows. In his chapter on land-floods, however, he expresses himself as follows: "They will (says he) always be found of great use where the sweepings of towns, farm-yards, &c. are carried down by them; seldom any other erection is wanting besides a sluice or small ware to divert and convey them over the lands. If the situation of the land happens to be on the side of a hill, catch-drains are absolutely necessary for watering the lower part of the hill, after the water has been used upon the upper. In many parts of the kingdom, where there are large hills or extensive rising lands, great quantities of water-run from them into the valleys after heavy rains: These might with proper attention be collected together before they get to the bottom or flat ground, and from thence be diverted to the purpose of watering those lands that lie below, with great advantage to the occupier, and at

Meadow. a small expence. And should the land thus situated be arable, yet it would be found a beneficial exchange to convert it into pasture; particularly if pasture-ground should be a desirable object to the occupier. The method of performing it is thus recommended. Observe the piece of land or field best adapted to the purpose, both for situation and soil. If it should be arable, make it first very level; and with the crop of corn sow all sorts of hay seeds; and as soon as it has got a green sward it may be laid out. In the lowest part of the ground draw a deep ditch for the current to run in through it; and continue it into some ditch or low part in the lands below, that the water may be freely carried off, after it has been and while it is in use. Draw ditches above the field intended to be watered assant the sides of the hill, in such a manner that they may all empty themselves into the head of the ditch above-mentioned, just where it enters the field to be watered: then erecting a ware across this ditch, the field will be capable of being watered, according to the situation of the ditch in the middle or on the side of the field. It must then be conveyed by small mains or trenches, and subdivided again by branch-trenches, according to the site of the field and the quantity of water that can be collected; trench-drains must be drawn, and the water conveyed into the ditch by means of tail-drains. A person unacquainted with water-meadows cannot conceive the advantage arising from water thus collected and conveyed over this species of water-meadow (if it may be so called), being generally a firm good soil; for the water running down from rich cultivated hills, eminences, &c. sweeps away with it, when the rain falls very heavy, vast quantities of dung dropped by sheep and other cattle, and the manure carried upon arable lands; all which being now diverted, and carried over the meadow with an easy descent, gives time for the particles of manure to subside upon the ground at one season, or of being filtered from it as it dribbles through the grafs at another; after which the warm weather pushes on vegetation amazingly. Meadows thus situated would be vastly superior to any other, if they had the advantage of a constant stream; but even as they are, taking the opportunity of watering them by every heavy rain or flood that happens, they will be found to be very valuable. The occupier of such lands is strenuously advised to let no time be lost in appropriating them to this use; because these lands are healthy for all kinds of cattle at almost all seasons; and the expence of converting them into this kind of water-meadow is exceeding small, the annual charges afterwards quite trifling, and the produce very considerable."

Mr Wright's directions for watering through the different months of the year. "In December and January, the chief care consists in keeping the land sheltered by the water from the severity of frosty nights. It is necessary, however, through the whole winter, every ten days or fortnight to give the land air, by taking the water off entirely, otherwise it would rot and destroy the roots of the grafs. It is necessary, likewise, that a proper person should go over every meadow at least twice every week, to see that the water is equally distributed, and to re-

move all obstructions arising from the continual influx of weeds, leaves, sticks, and the like. In February, a great deal depends upon care and caution. If you now suffer the water to remain on the meadow for many days without intermission, a white scum is raised, very destructive to the grafs; and if you take off the water, and expose the land to a severe frosty night, without its being previously dried for a whole day, the greatest part of the tender grafs will be cut off. The only ways to avoid both these injuries are, either to take the water off by day to prevent the scum, and to turn it over again at night to guard against the frost; or, if this practice be too troublesome, both may be prevented by taking the water entirely off for a few days and nights, provided the first day of taking off be a dry one; for if the grafs experience one fine drying day, the frost at night can do little or no injury. The scum is generated chiefly by the warmth of the sun, when the water is thin and used too plentifully. Towards the middle of this month we vary our practice in watering, by using only about half the quantity of water which is made use of earlier in the winter, all that is now required being to keep the ground in a warm moist state, and to force vegetation.

"At the beginning of March, the crop of grafs in the meadows is generally sufficient to afford an abundant pasturage for all kinds of stock, and the water is taken off for near a week, that the land may become dry and firm before the heavy cattle are turned in.—It is proper, the first week of eating off the spring-feed, if the sea-n be cold, to give the cattle a little hay each night."

"It is a custom (says Mr Wright) with some farmers in Hampshire, to eat off the spring-graſs of their meadows with ewes and lambs, in the same manner that we do a field of turnips, by inclosing a certain portion each day with hurdles or stakes, and giving them hay at the same time. This is certainly making the most of the grafs, and an excellent method to fine and sweeten the future herbage. In this month and April, you may eat the grafs as short and close as you please, but never later; for if you trespass only one week on the month of May, the hay-crop will be very much impaired, the grafs will become soft and woolly, and have more the appearance and quality of an after-math than a crop. At the beginning of May, or when the spring feeding is finished, the water is again used for a few days by way of wetting."

"It is rather remarkable, that watering in autumn, winter, or spring, will not produce that kind of herbage which is the cause of the rot in sheep; but has been known to remove the cause from meadows, which before had that baneful effect. If, however, you use sheep the water only a few days in any of the summer months, all the lands thus watered will be rendered unsafe for the pasturage of sheep. Of this I was lately convinced from an experiment made by a friend. At the beginning of July, when the hay was carried off, and the water rendered extremely muddy and abundant by several days rain, he thought proper to throw it over his meadows for ten days, in which time a large collection of extremely rich manure was made upon the land. In about a month the meadow was covered with uncommon luxuriancy and blackness of herbage. Into this grafs were turned eight

^{Meadow.} eight found ewes and two lambs. In six weeks time the lambs were killed, and discovered strong symptoms of rotteness; and in about a month afterwards one of the ewes was killed, and though it proved very fat, the liver was putrid and replete with the insect called the *fish*, or *swarm*: the other ewes were sold to a butcher, and all proved unsound. This experiment, however, convinces me, by the very extraordinary improvement made thereby in the meadow, that muddy water in the summer is much more enriching than it is in autumn or winter; and ought, therefore, to be used for a week at least every wet summer, notwithstanding its inconveniences to sheep, the most profitable species of stock."

Mr Boswell, besides his general directions for watering, gives many plans of the ditches, drains, &c. for particular meadows, some of them done from an actual survey. But these being confined to particular situations, we shall here only speak of his method in general. In his third chapter, intitled *A general Description of Water-meadows*, he observes, that "lands capable of being watered, lie sometimes only on one side and sometimes on both sides of the stream designed to supply them with water. In the former case, when they have a pretty quick descent, the land may be often watered by a main drawn out of the stream itself, without any ware; though he acknowledges that it is by far the best way to erect a ware, and to draw mains on each side, to dispose of the water to the best advantage.

Boggy lands require more and longer continued watering than such as are sandy or gravelly; and the larger the body of water that can be brought upon them, the better. The weight and strength of the water will greatly assist in compressing the soil, and destroying the roots of the weeds that grow upon it; nor can the water be kept too long upon it, particularly in the winter season; and the closer it is fed, the better.

To improve clay soils, we must endeavour to the utmost to procure the greatest possible descent from the trench to the trench drain; which is best done by making the trench-drains as deep as possible, and applying the materials drawn out of them to raise the trenches. Then, with a strong body of water, taking the advantage of the autumnal floods, and keeping the water some time upon them at that season, and as often as convenient during the winter, the greatest improvement on this sort of soils may be made.

Warm sand or gravelly soils are the most profitable under the watering system, provided the water can be brought over them at pleasure. In soils of this kind, the water must not be kept long at a time, but often shifted, thoroughly drained, and the land frequently refreshed with it: under which circumstances the profit is immense. A spring-feeding, a crop of hay, and two aftermaths, may be obtained in a year; and this, probably, where in a dry summer scarce grass enough could be found to keep a sheep alive. If the stream be large, almost any quantity of land may be watered from it; and though the expence of a ware over it is great, it will soon be repaid by the additional crop. If the stream is small, the expence will be so in proportion.

The following method of improving a water-me-

dow that was springy has been tried by Mr Boswell with success. The meadow had been many years watered by a spring rising just above it from a barren sandy heath; the soil near the surface was in some places a gravelly sand, in others a spongy cork, both upon a strong clay and sand mixture, which retained the draining of the lands above it. Whenever it had been watered, and left to drain itself dry, a yellowish-red water stood in many parts, and oozed out of others; the herbage being no other than a poor, miserable, hairy grass and small sedge. Chalk and ashes had been thrown over it to very little purpose. It was then drained underground almost all the different descents, and all these drains carried into one large drain, which had been already cut for the purpose of carrying off the water when the meadow was overflowed. These drains were cut quite through the mixture of clay and sand, and as much deeper as the fall of the ground below would admit of; then, with chalk cut for the purpose, small hollow drains were formed at the bottom of these; the drains were then filled up with the materials that came out.

This was done in the beginning of summer, and the work frequently examined through the season; the soil was found firmer than before, and none of that nasty red water to be met with upon the surface, though it continually oozed into the drains. In autumn the meadow was again prepared for waterings, by repairing those trenches and drains that were properly situated; cutting others where wanted, for the purpose of watering meadows. The water being then brought over it from the same spring as before, the event answered the most sanguine wishes of the proprietor; the effects were visible the first year, and the ground has been constantly improving ever since.

Mr Boswell also informs us, that a gentleman in Scotland had applied to him for directions to water some lands lying on the sides of hills, where the descent is quick; and of which there are many in this country, as well as in the north of England. It would be difficult to water such lands by means of drains and trenches according to the directions already given; because the bends in the trenches must be very near together and large, as the water must flow out of the trench above the bend to flow over the pane below it; the number and size would likewise be inconvenient, and greatly offend the eye.

Lands of this sort are generally capable of being ploughed; in which case our author directs them to be once ploughed in the spring, and sown with oats or any other kind of grain that will rot the furrow. When the grain is harvested, plough the land across; the last ploughing with the Kentish plough, which has a moveable mold-board, and is called a *turn-wrist* plough. This turns the furrows down the side of the hill, the horses going forwards and backwards in the same furrows. By this means the land is laid flat without any open furrows in it: drest it down in the spring very fine, and sow it with oats, and mix with some kinds of grass seeds very thick. Thus the ground will have but few irregularities; and as soon as the corn is carried off, or the following spring at farthest, the mains and drains may be cut out.

For watering coarse lands that are firm enough to bear

^{Meadow.}

²⁵ Method of improving a springy water-meadow.

²⁴ Mr Boswell's general directions for watering.

Meadow. bear the plough, and situated near a stream, our author gives the following directions.

27
Of water-
ing coarse
lands.

"Let the land thus situated be ploughed once in the spring, and sown with any grain that will rot fward. As soon as the crop is off, plough it again, and leave it rough through the winter. Work it down early in the spring, and plough it in the direction the trenches are to lie, making the ridges of a proper size for watering, ten or twelve yards wide for instance; work it fine; then gather the ridges up again in the same manner, making the last furrows of each ridge as deep as possible. If the land be not fine, dress it down again, and gather it up a second time if necessary; and with a shovel throw the earth from the edges of the furrows to the tops of the ridges, to give the greatest possible descent from the trench to the drain. Sow it with oats and grafs seeds very thick; and after the corn is carried off, the trenches may be formed upon the top of each ridge, dispersing the furrows with a spade as much as the fall of the land will admit of for the drains; taking care to procure sufficient fall at all events, to drain the lands after they have been watered. By this method the crops of corn will nearly pay all the expence, and the land will be in excellent order.

28
Of the ma-
nagement
of mea-
dows after
watering.

After the work of watering a meadow is totally finished, and the hay carried off, cattle may be let in to eat the after-math. When this is done, it will then be necessary to examine whether or not the mains have suffered any injury from their feet; whether there be quantities of mud or sand collected at the angles, &c. all of which must be thrown out and the breaches repaired; by which means the trenches, drains, &c. will last three years, but otherwise not more than two. The roots, mud, &c. may be used in repairing the breaches, but never left upon the sides of the trenches out of which they are taken. The tail-drains require to be cleaned oftener than any of the other works, for this obvious reason, that the mud, &c. is carried down from all the others into them; where if it be allowed to accumulate, it occasions a stagnation of water upon the meadow itself. In repairing the trenches, particular care ought to be taken that the workmen do not make them any wider than before, which they are very apt to do; neither are they to be allowed to throw the materials which they dig out in a ridge behind the edge of the trench, which both widens it and promotes weeds.

29
Of the
water
should con-
tinue upon
the mea-
dows.

During the time of watering, it will be necessary to examine the meadow every two or three days in order to remove obstructions, &c. If the drains should be filled with water and run over, they ought to be made deeper; or if this cannot be done, they should be widened. In the winter time a regular strong water should be kept, avoiding very strong great floods. In this season the water may be kept on the ground with safety for a month or even six weeks if the soil be corky or boggy or a strong clay; but not quite so long if it be gravel or sand. At the second watering a fortnight or three weeks will be sufficient; and after Candlemas a fortnight will be rather too long. At the third watering a week will be sufficient, which will bring it to about the middle of March; by which time, if the weather be tolerably mild, the grafs will be long enough for the ewes and lambs, or for fattening

lambs; which may then be turned into the meadow with great advantage. Even in the end of February, if the winter has been very mild, the grafs will be long enough for them. Here they may be permitted to feed till the beginning of May, changing them into different meadows. As soon as they are taken out, the water must be turned in for a week, carefully examining every trench and drain for the reasons already given. The water is then to be shifted into others, alternately watering and draining, lessening the time the water remains upon it as the weather grows warmer; and in five, six, or seven weeks, the grafs will be fit to be mown for hay, and produce from one to two tons, or even more, an acre upon good ground.

Mr Boswell directs, that about a week before the grafs is to be mown the water should be let into the meadow for 24 hours; which, he says, will make the ground moist at the bottom, the scythe will go thro' it the more easily, and the grafs will be mown closer to the ground. This practice, however, is entirely disapproved of by Mr Wright. "Though it may prevail in Dorsetshire (says he), it is very feldom advisable, for the following reasons: Water made to run through a thick crop of grafs, though it may appear ever so pure, will leave a certain quantity of adherent scum or sediment, which can never be separated from the hay, but will render it unpalatable, if not prejudicial, to the cattle that eat it. And this wetting of the land and grafs will impede the drying or making of the hay perhaps some days, which in difficult seasons is of very great consequence; and it will likewise make the turf too soft and tender to support the wheels of a loaded waggon in carrying off the hay. Besides, there is reason to believe that one day's wetting in the summer will, upon most meadows, endanger the soundness of every sheep that feeds upon the after-math."

The spring-feeding ought never to be done by heavier cattle than sheep or calves; for larger cattle do much hurt by poaching the ground with their feet, destroying the trenches, and spoiling the grafs. Mr Boswell likewise greatly recommends a proper use of spring floods, from which he says much benefit may be derived; but if there is any quantity of grafs in the meadows not eaten, these floods must be kept out, otherwise the grafs will be spoiled; for they bring with them such quantities of sand and mud, which stick to the grafs, that the cattle will rather starve than taste it. Great quantities of cgrafs or aftermath are frequently spoiled in flat countries by the floods which take place in the fall. In the winter-time, however, when the ground is bare, the sand and mud brought down by the floods is soon incorporated with the soil, and becomes an excellent manure. The certain rule with regard to this matter is, "Make use of the floods when the grafs cannot be used; avoid them when the grafs is long or soon to be cut."

"It has often been a subject of dispute (says Mr Boswell), whether, from the latter end of autumn to Candlemas, the throwing a very strong body of water, where it can be done, over the meadows, is of any essential service or not? Those who consider it as advantageous, assert, that when the waters run rude and strong over the ground, they beat down and rot the tufts

ing from
the end of
autumn to
Candlemas.

Meadow.

tufts of foggy or rough grass, sedge, &c. that are always to be found in many parts of coarse meadow-ground; and therefore are of peculiar service to them. On the other side it is alleged, that by coming in so large a body, it beats the ground (in the weak places particularly) so bare, that the sward is destroyed; and also brings with it such quantities of seeds of weeds, that at the next hay season the land in all those bare places bears a large burden of weeds, but little grass.

"The general opinion of the watermen upon this point is, that in water meadows which are upon a warm, sandy, or gravelly soil, with no great depth of loam upon them, rude strong watering, even in winter, always does harm without any possible essential service. On the contrary, cold strong clay land will bear a great deal of water a long time without injury; and boggy, corky, or spongy soil, will also admit of a very large and strong body of water upon it; provided the drains are made wide and deep enough to carry it off, without forcing back upon the end of the panes, with great advantage for almost any length of time at that season. The weight and force of the water vastly assists in compressing those soils, which only want solidity and tenacity to make them produce great burthens of hay: nothing, in their opinion, corrects and improves those soils so much as a very strong body of water, kept a considerable time upon them at that season."

Notwithstanding the above reasons, however, Mr Boswell informs us, That he has doubts upon the subject; nor can he by any means acquiesce in this opinion, unless by rude strong waters he is permitted to understand only rather a larger quantity of water conveyed over the land at this early season than ought to be used in the spring or summer: unmanageable waters he believes always hurtful.

"It may be proper just to add (continues he), that as soon as the hay is carried off the meadows, cattle of any sort except sheep may be put to eat the grass out of the trenches, and what may be left by the mowers. This perhaps will last them a week; when the water may be put into the meadows in the manner already described, taking care to mow the long grass which obstructs the water in the trenches; and this mowing is best done when the water is in them. Let the weeds, leaves, &c. be taken out and put in heaps, to be carried away into the farm-yards; examine the trenches, make up the breaches, &c. take particular care that the water only dribbles over every part of the panes as thin as possible, this being the warmest season of the year. The first watering should not be suffered to last longer than two or three days before it is shifted off (and if the season be wet, perhaps not so long, as warmth seems to be the greatest requisite after the land is once wet to assist vegetation) to another part or meadow beat out by the cattle, by this time fit to take it. Do by this meadow exactly the same, and so by a third and fourth, if as many meadows belong to the occupier. Observe at all times, when the water is taken out of a meadow, to draw up the drain-slucce hatches; as, without doing that, watering is an injury. By the time that three or four parts are thus regularly watered, the first will have an after-math, with such rich and beautiful verdure as will be astonishing; and both quantity and quality will be beyond conception better than if the lands had not been watered.

Meadows:
Meal.

"Hence we see why every person should if possible have three or four meadows that can be watered; for here, while the cattle are eating the first, the second is growing, the third draining, &c. and the fourth under water. In this manner the after-math will in a mild season last till Christmas. A reason was given why the spring-grass should be fed only by sheep or calves; a reason equally cogent may be given, why the after-grass ought not to be fed by them, because it will infallibly rot them. "No sheep (says our author), except those which are just fat, must ever be suffered even for an hour in water-meadows except in the spring of the year; and even then care must be taken that every part of the meadows have been well watered, and that they are not longer kept in them than the beginning of May. Although at present it is unknown what is the occasion of the rot, yet certain it is that even half an hour's feeding in unhealthy ground has often proved fatal. After a short time they begin to lose their flesh, grow weaker and weaker: the best feeding in the kingdom cannot improve them after they once fall away; and when they die, animalcula like plaice are found in the livers. Scarcely any ever recover from a slight attack; but when farther advanced, it is always fatal. Guard by all means against keeping the water too long upon the meadow in warm weather; it will very soon produce a white substance like cream, which is prejudicial to the grass, and shows that it has been too long upon the ground already. If it be permitted to remain a little longer, a thick scum will settle upon the grass of the consistence of glue, and as tough as leather, which will quite destroy it wherever it is suffered to be produced. The same bad effects seem to arise from rude waters; neither can the scum easily be got off.

"Rolling meadows in the spring of the year is an excellent method. It should be done after Candlemas, when the meadow has been laid dry a week. It should be always rolled lengthwise of the panes, up one side of the trench and down the other. Rolling also contributes much to the grass being cut close to the surface when mown, which is no small advantage; for the little hillocks, spawnings of worms, ant-hills, &c. are by this means pressed close to the ground, which would otherwise obstruct the scythe and take off its edge; and to avoid that inconvenience, the workmen always mow over them."

MEAL, the flour of grain. The meal or flour of Britain is the finest and whitest in the world. The French is usually browner, and the German browner than that. Our flour keeps well with us, but in carrying abroad it often contracts damp, and becomes bad. All flour is subject to breed worms; these are white in the white flour, and brown in that which is brown: they are therefore not always distinguishable to the eye; but when the flour feels damp, and smells rank and musty, it may be conjectured that they are there in great abundance.

The colour and the weight are the two things which denote the value of meal or flour; the whiter and the heavier it is, other things being alike, the better it always is. Pliny mentions these two characters as the marks of good flour; and tells us, that Italy in his time produced the finest in the world. This country indeed was famous before his time for

meadows.

33
Advantage
of rolling
meadows.

Meal.

this produce; and the Greeks have celebrated it; and Sophocles in particular says, that no flour is so white or so good as that of Italy. The corn of this country has, however, lost much of its reputation since that time; and the reason of this seems to be, that the whole country being full of sulphur, alum, vitriol, marcasites, and bitumens, the air may have in time affected them so far as to make them diffuse themselves through the earth, and render it less fit for vegetation; and the taking fire of some of these inflammable minerals, as has sometimes happened, is alone sufficient to alter the nature of all the land about the places where they are.

The flour of Britain, though it pleases by its whiteness, yet wants some of the other qualities valuable in flour; the bread that is made of it is brittle and does not hold together, but after keeping a few days becomes hard and dry as if made of chalk, and is full of cracks in all parts; and this must be a great disadvantage in it when intended for the service of an army or the like occasions, where there is no baking every day, but the bread of one making must necessarily be kept a long time.

The flour of Picardy is very like that of Britain; and after it has been kept some time, is found improper for making into paste or dough. The French are forced either to use it immediately on the grinding, or else to mix it with an equal quantity of the flour of Brittany, which is coarser but more unctuous and fatty; but neither of these kinds of flour keep well.

The flour of almost any country will do for the home consumption of the place, as it may be always fresh ground; but the great care to be used in selecting it is in order to the sending it abroad, or furnishing ships for their own use. The saline humidity of the sea-air rusts metals, and fouls every thing on board, if great care be not taken in the preserving them. This also makes the flour damp and mouldy, and is often the occasion of its breeding insects, and being wholly spoiled.

The flour of some places is constantly found to keep better at sea than that of others; and when that is once found out, the whole caution needs only be to carry the flour of those places. Thus the French find that the flour of Poitou, Normandy, and Guienne, all bear the sea-carriage extremely well; and they make a considerable advantage by carrying them to their American colonies.

The choice of flour for exportation being thus made, the next care is to preserve it in the ships: the keeping it dry is the grand consideration in regard to this; the barrels in which it is put up ought to be made of dry and well-seasoned oak, and not to be larger than to hold two hundred weight at the most. If the wood of the barrels have any sap remaining in it, it will moisten and spoil the flour; and no wood is so proper as oak for this purpose, or for making the bins and other vessels for keeping flour in at home, since when once well dried and seasoned it will not contract humidity afterwards. The beech-wood, of which some make their bins for flour, is never thoroughly dry, but always retains some sap. The fir will give the flour a taste of turpentine; and the ash is always subject to be eaten by worms. The oak is preferable, because of its being free from these faults; and when the several

kinds of wood have been examined in a proper manner, there may be others found as fit, or possibly more so, than this for the purpose. The great test is their having more or less sap. See *Flour* and *Wood*.

MEAN, in general, denotes the middle between two extremes: thus we say the mean distance, mean proportion, &c.

MEARNS, or KINCARDINSHIRE, a county of Scotland, bounded on the north by Aberdeenshire, on the east by the British Ocean, and on the south-west by Angushire. In form it resembles a harp, having the lower point towards the south. Its length along the coast is scarce 30 miles; its greatest breadth about 20. Some derive the first name from Mearns a valiant nobleman, who, subduing the country, received it in reward from his prince Kenneth II. Camden, with much probability, supposes it to retain part of the name of the old inhabitants, the Vernicones of Ptolemy, it being common for the Britons in discourse to change the V into M. The other name is taken from its ancient capital *Kincardine*, now an inconsiderable village. The tract of country through which the Dee passes, and the plain along the sea-coast, are well cultivated, and produce much corn and flax. The fields are in many places screened by woods; and the heaths afford sheep-walks and much good pasture for cattle. Near Stonehaven, to the south, are the ruins of Dunottar castle, the ancient seat of the earls Marischal of Scotland, situated on a high perpendicular rock, almost surrounded by the sea. In this neighbourhood is a precipitous cliff over-hanging the sea, called *Fossil's Cleugh*; noted as the resort of kittiwakes, the young of which are much sought after in the hatching season, being esteemed a great delicacy.—At a little distance from Stonehaven, up the river, stands Urie, the birth-place of Barclay the famous apologist for the Quakers. The Quakers have here a burying ground; and in the vicinity are seen the traces of a Roman station. The great valley called *Strathmore* commences here, and extends in a south-west direction nearly as far as Benlomond in Stirlingshire, bounded all along to the north-west by the Grampian mountains.—The village of Fordun, a little south from the centre of the country, is supposed to be the birth-place of the celebrated author of the *Scotchichronicon*. St Paddy's church, or Paldy kirk in this neighbourhood, is famous for being the burial-place and residence of St Palladius; whose chapel is still to be seen on the south side of it, 40 feet by 18, now the burial-place of the Halkerton-family. Near the village, and along the river Bervie, the country is flat and well cultivated. The small town of *INVERBERVIE* was made a royal borough by David Bruce, who landed there with his queen at Craig David after his long retreat into France. Near the village of *Fettercairn* was Den Finnel, the residence of Finella, daughter of a nobleman of large possessions in this country, or, as Major calls her, *countess of Angus*, who was accessory to the murder of Kenneth II. About two miles from this place, on the road-side, is a cairn of a stupendous size and uncommon form, which probably might give name to the parish. About six miles west from Bervie, is situated *Laurence-kirk*, which some years back was only an insignificant village of six or seven houses; but by the judicious and liberal exertions of its proprietor Lord Gardenstone, has

Measures,
Measure.

has become a handsome little town, with a right to elect magistrates, and to hold an annual fair and a weekly market. He has established here a flourishing and extensive manufacture of lawn, cambric, linen, and various other articles. He has also freely renounced all the oppressive services due by his tenants; services which have been so long and so justly complained of as a check to agriculture in many parts of Scotland.—The north-west part of the shire, being mountainous, is more employed in pasture than in cultivation.

MEASLES, a cutaneous disease attended with a fever, in which there is an appearance of eruptions that do not tend to a suppuration. See (the *Index* subjoined to) **MEDICINE**.

MEASURE, in geometry, denotes any quantity assumed as one, or unity, to which the ratio of the other homogeneous or similar quantities is expressed.

MEASURE, in a legal and commercial sense, denotes a certain quantity or proportion of any thing, bought, sold, valued, or the like.

It is necessary, for the convenience of commerce, that an uniformity should be observed in weights and measures, and regulated by proper standards. A foot-rule may be used as a standard for measures of length, a bushel for measures of capacity, and a pound for weights. There should be only one authentic standard of each kind, formed of the most durable materials, and kept with all possible care. A sufficient number of copies, exactly corresponding to the principal standard, may be distributed for adjusting the weights and measures that are made for common use. There are several standards of this kind both in England and Scotland. See the article *WEIGHTS and Measures*.

If any one of the standards above-mentioned be justly preserved, it will serve as a foundation for the others, by which they may be corrected if inaccurate, or restored if entirely lost. For instance, if we have a standard foot, we can easily obtain an inch, and can make a box which shall contain a cubical inch, and may serve as a standard for measures of capacity. If it be known that a pint contains 100 cubical inches, we may make a vessel five inches square, and four inches deep, which will contain a pint. If the standard be required in any other form, we may fill this vessel with water, and regulate another to contain an equal quantity. Standards for weights may be obtained from the same foundation; for if we know how many inches of water it takes to weigh a pound, we have only to measure that quantity, and the weight which balances it may be assumed as the standard of a pound.

Again, if the standard of a pound be given, the measure of an inch may be obtained from it: for we may weigh a cubical inch of water, and pour it into a regular vessel; and having noticed how far it is filled, we may make another vessel of like capacity in the form of a cube. The side of this vessel may be assumed as the standard for an inch; and standards for a foot, a pint, or a bushel, may be obtained from it. Water is the most proper substance for regulating standards; for all other bodies differ in weight from others of the same kind; whereas it is found by experience that spring and river water, rain, and melted

snow, and all other kinds, have the same weight; and this uniformly holds in all countries where the water is pure, alike warm, and free from salt and minerals.

Thus, any one standard is sufficient for restoring all the rest. It may further be desired to hit on some expedient, if possible, for restoring the standards, in case that all of them should ever fall into disorder, or should be forgotten, through the length of time, and the vicissitudes of human affairs. This seems difficult, as no words can convey a precise idea of a foot-rule, or a pound weight. Measures, assumed from the dimensions of the human body, as a foot, a hand-breadth, or a pace, must nearly be the same in all ages, unless the size of the human race undergo some change; and therefore, if we know how many square feet a Roman acre contained, we may form some judgment of the nature of the law which restricted the property of a Roman citizen to seven acres; and this is sufficient to render history intelligible; but it is too inaccurate to regulate measures for commercial purposes. The same may be said of standards, deduced from the measure of a barley-corn, or the weight of a grain of wheat. If the distance of two mountains be accurately measured and recorded, the nature of the measure used will be preserved in a more permanent manner than by any standard; for if ever that measure fall into disuse and another be substituted in its place, the distance may be measured again, and the proportion of the standards may be ascertained by comparing the new and ancient distances.

But the most accurate and unchangeable manner of establishing standards is, by comparing them with the length of pendulums. The longer a pendulum is, it vibrates the slower; and it must have one precise length in order to vibrate in a second. The slightest difference in length will occasion a difference in the time; which will become abundantly sensible after a number of vibrations, and will be easily observed if the pendulum be applied to regulate the motion of a clock. The length of a pendulum which vibrates seconds in London is about 39½ inches, is constantly the same at the same place; but it varies a little with the latitude of the place, being shorter as the latitude is less. Therefore, though all standards of weights and measures were lost, the length of a second pendulum might be found by repeated trials: and if the pendulum be properly divided, the just measure of an inch will be obtained; and from this all other standards may be restored. See *Whitehurst on Invariable Measures*.

Measures are various, according to the various kinds and dimensions of the things measured.—Hence arise lineal or longitudinal measures, for lines or lengths; square measures, for areas or superficies; and solid or cubic measures, for bodies and their capacities: all which again are very different in different countries and in different ages, and even many of them for different commodities. Whence arise other divisions of ancient and modern measures, domestic and foreign ones, dry measures, liquid measures, &c.

I. *Long Measures, or Measures of Application.*

1.] *The English and Scotch Standards.*

The English lineal standard is the yard, containing 3 English feet; equal to 3 Paris feet 1 inch and ⅔.

of an inch, or $\frac{2}{3}$ of a Paris ell. The use of this measure was established by Henry I. of England, and the standard taken from the length of his own arm. It is divided into 36 inches, and each inch is supposed equal to 3 barley-corns. When used for measuring cloth, it is divided into four quarters, and each quarter subdivided into 4 nails. The English ell is equal to a yard and a quarter, or 45 inches, and is used in measuring linens imported from Germany and the Low-Countries.

The Scots *elwand* was established by king David I. and divided into 37 inches. The standard is kept in the council-chamber of Edinburgh, and being compared with the English yard, is found to measure $37\frac{1}{2}$ inches; and therefore the Scots inch and foot are larger than the English, in the proportion of 180 to 185; but this difference being so inconsiderable, is seldom attended to in practice. The Scots ell, though forbidden by law, is still used for measuring some coarse commodities, and is the foundation of the land-measure of Scotland.

Itinerary measure is the same both in England and Scotland. The length of the chain is 4 poles, or 22 yards; 80 chains make a mile. The old Scots computed miles were generally about a mile and a half each.

The reel for yarn is $2\frac{1}{2}$ yards, or 10 quarters, in circuit; 120 threads make a cut, 12 cuts make a hank or hank, and 4 hanks make a spindle.

2.] The French Standard is the aune or ell, containing 3 Paris feet 7 inches 8 lines, or 1 yard $\frac{1}{4}$ English; the Paris foot royal exceeding the English by $\frac{63}{100}$ parts, as in one of the following tables. This ell is divided two ways, viz. into halves, thirds, sixths, and twelfths; and into quarters, half-quarters, and sixteenths.

This ell holds throughout the greatest part of France; excepting at Troyes in Champagne, at Arc in the Barrois, and in some parts of Picardy and Burgundy, where the ell contains only 2 feet 5 inches 1 line; in Bretagne, where it contains 4 feet 2 inches 11 lines; and at St Genoux in Berry, where it exceeds the Paris ell by 8 lines. See ELL. But in Languedoc, particularly at Marfeilles, Montpellier, Thoulouse in Provence, and in Guienne, they measure by the canna, which at Thoulouse and in Guienne contains 5 Paris feet 5 inches and 6 lines; or one Paris ell and a half. But at Montpellier, and throughout the Lower Languedoc, as also in Provence and Avignon, and even Dauphine, the canna is 6 feet and 9 lines, or 1 Paris ell and $\frac{3}{4}$. See CANNA.

We have lately had some accurate comparisons between some of the French weights and measures and those of England, the result of which is, (1.) The Paris half toise, as set off on the standard kept in the Royal Society; contains of English inches by the same standard 38.355, whence it appears, that the English yard and foot is, to the Paris half toise and foot, nearly as 107 to 114; for as 107 to 114, so is 36 to 38.35514.

(2.) The Paris 2 marc, or 16 ounce weight, weighs English Troy grains 7560; whence it appears, that the English Troy pound of 12 ounces, or 5760 grains, is to the Paris 2 marc, or 16 ounce weight, as 16 to 21; that the Paris ounce weighs English Troy grains

472.5, and that consequently, the English Troy ounce is to the Paris ounce as 64 is to 63.

(3.) The English Avoirdupois pound weighs Troy grains 7004; whence the Avoirdupois ounce, whereof 16 make a pound, is found equal to 437.75 Troy grains.—And it follows, that the Troy pound is to the Avoirdupois pound as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7003.636; that the Troy ounce is to the Avoirdupois ounce, as 80 to 73 nearly; for as 80 to 73, so is 480 to 438. And, lastly, that the Avoirdupois pound and ounce is to the Paris two marc weight and ounce, as 63 to 68 nearly; for as 63 to 68, so is 7004 to 7559.873. See WEIGHT.

(4.) The Paris foot expressed in decimals, is equal to 1.0654 of the English foot, or contains 12.785 English inches. See FOOT.

3.] The standard in Holland, Flanders, Sweden, a good part of Germany, many of the Hans-towns, as Dantzick, and Hamburg, and at Geneva, Frankfort, &c. is likewise the ell: but the ell, in all these places, differs from the Paris ell. In Holland, it contains one Paris foot eleven lines, or four sevenths of the Paris ell. The Flanders ell contains two feet one inch five lines and half a line; or seven-twelfths of the Paris ell. The ell of Germany, Brabant, &c. is equal to that of Flanders.

4.] The Italian measure is the braccio, brace, or fathom. This obtains in the states of Modena, Venice, Florence, Lucca, Milan, Mantua, Bologna, &c. but is of different lengths. At Venice, it contains one Paris foot eleven inches three lines, or eight fifteenths of the Paris ell. At Boulogna, Modena, and Mantua, the brace is the same as at Venice. At Lucca it contains one Paris foot nine inches ten lines, or half a Paris ell. At Florence, it contains one foot nine inches four lines, or forty-nine hundredths of a Paris ell. At Milan, the brace for measuring of silks is one Paris foot seven inches four lines, or four-ninths of a Paris ell: that for woollen cloths is the same with the ell of Holland. Lastly, at Bergama, the brace is one foot seven inches six lines, or five-ninths of a Paris ell. The usual measure at Naples, however, is the canna, containing six feet ten inches and two lines, or one Paris ell and fifteen seventenths.

5.] The Spanisb measure is the vara or yard, in some places called the barra; containing seventeen twenty-fourths of the Paris ell. But the measure in Castile and Valencia is the pan. span, or palm; which is used, together with the canna, at Genoa. In Aragon, the vara is equal to a Paris ell and a half, or five feet five inches six lines.

6.] The Portuguese measure is the cavedos, containing two feet, eleven lines, or four-sevenths of a Paris ell; and the varra, a hundred and six whereof make a hundred Paris ells.

7.] The Piedmontese measure is the ras, containing one Paris foot nine inches ten lines, or half a Paris ell. In Siçily, their measure is the canna, the same with that of Naples.

8.] The Muscovite measures are the cubit, equal to one Paris foot four inches two lines; and the arin, two whereof are equal to three cubits.

9.] The Turkish and Levant measures are the picq, containing two feet two inches and two lines, or three fifths of the Paris ell. The Chinese measure, the

cobre;

Measure. cobre; ten whereof are equal to three Paris ells. In Persia, and some parts of the Indies, the guezze, whereof there are two kinds; the royal guezze, called also the *guezze monkeffer*, containing two Paris feet ten inches eleven lines, or four-fifths of the Paris ell; and the shorter guezze, called simply *guezze*, only two thirds of the former. At Goa and Oimuz, the measure is the vara, the same with that of the Portuguese, having been introduced by them. In Pegu, and some other parts of the Indies, the cando or candi, equal to

the ell of Venice. At Goa, and other parts, they use a larger cando, equal to seventeen Dutch ells; exceeding that of Babel and Balfora by $\frac{7}{8}$ per centum, and the vera by 64. In Siam, they use the ken, short of three Paris feet by one inch. The ken contains two foks, the fok two keubs, the keub twelve nious or inches, the niou to be equal to eight grains of rice, i. e. to about nine lines. At Cambioa, they use the hafter; in Japan, the tatam; and the span on some of the coasts of Guinea.

8. Different Itinerary Measures.

A French league is about 2 $\frac{1}{2}$ English miles
A German mile 4 ditto
A Dutch mile 3 $\frac{1}{2}$ ditto
An Italian mile 1 $\frac{1}{2}$ ditto
A Spanish league 3 $\frac{1}{2}$ ditto
A Russian verit 3 ditto

II. SQUARES, SUPERFICIAL, OF LAND MEASURE.

1.] *English* square measures are raised from the yard of 36 inches multiplied into itself, and thus producing 1296 square inches in the square yard; the divisions of this are square feet and inches; and the multiples, poles, roods, and acres. Because the length of a pole is 5 $\frac{1}{2}$ yards, the square of the same contains 30 $\frac{1}{4}$ square yards. A square mile contains 640 square acres. In measuring fens and woodlands, 18 feet are generally allowed to the pole, and 21 feet in forest lands.

A hide of land, frequently mentioned in the earlier part of the English history, contained about 100 arable acres; and 5 hides were esteemed a knight's fee. At

the time of the Norman conquest, there were 243,600 hides in England.

2.] *Scotch* square or land measure is regulated by the Scotch ell: 36 square ells = 1 fall, 40 falls = 1 rood, 4 roods = 1 acre.—The proportion between the Scotch and English acre, supposing the feet in both measures alike, is as 1369 to 1089, or nearly as 5 to 4. If the difference of the feet be regarded, the proportion is as 10,000 to 7869. The length of the chain for measuring land in Scotland is 24 ells, or 74 feet.—A husband-land contains 6 acres of fock and scythe land, that is, of land that may be tilled with a plough or mown with a scythe: 13 acres of arable land make one ox-gang, and 4 ox-gangs make a pound-land of old extent.

3.] *French* square measures are regulated by 12 square lines in the inch square; 12 inches in the foot, 22 feet in the perch, and 100 perches in the arpent, or acre.

TABLES of SQUARE MEASURE.

I. ENGLISH.

Inches	Feet	Yards	Paces	Poles	Rood	Acres
144	12	3	4	1		
1296	36	9	12	3		
3600	60	25	27	10.89		
39204	272 $\frac{1}{4}$	30 $\frac{1}{2}$	40	10.89		
1568160	10890	1210	435.6	40		
6272640	43560	4840	1743.6	160	4	1

2. *Grecian* square measures were the plethron or acre; by some said to contain 1444, by others 10,000 square feet; and aroura the half of the plethron. The aroura of the Egyptians was the square 100 cubits.

3. *Roman* square measure reduced to English. The integer was the jugerum or acre, which the Romans divided like the libra or as: thus the jugerum contained

	square feet.	square paces.	square rods.	square poles.	square feet.
As	28800	288	2	18	250.05
Deunx	26400	264	2	10	183.85
Dextans	24000	240	2	2	117.64
Dodrans	21600	216	1	3 $\frac{1}{4}$	51.4

Septunx	16800	168	1	17	191.25
Semis	14400	144	1	9	125.05
Quincunx	12000	120	1	1	58.82
Triens	9600	96	0	32	264.85
Quadrans	7200	72	0	24	198.64
Sextans	4800	48	0	16	132.43
Uncia	2400	24	0	8	66.21

Note, A $\frac{1}{2}$ Actus major was 14,400 square feet, equal to a semis; clima, 3600 square feet, equal to a sextans; and actus minimus equal to a sextans.

III. CUBICAL Measures, or Measures of Capacity, for LIQUIDS.

1.] The *English* measures were originally raised from troy-weight : it being enacted by several statutes, that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, should weigh a gallon of wine measure, the divisions and multiples whereof were to form the other measures ; at the same time it was also ordered, that there should be but one liquid measure in the kingdom : yet custom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a second standard gallon adjusted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter standard are raised two several measures, the one for ale, the other for beer. The sealed gallon at Guildhall, which is the standard for wines, spirits, oils, &c. is supposed to contain 231 cubic inches ; and on this supposition the other measures raised therefrom, will contain as in the table underneath : yet, by actual experiment, made in 1683, before the lord-mayor and the commissioners of excise, this gallon was found to contain only 224 cubic inches : it was however agreed to continue the common supposed contents of 231 cubic inches ; so that all computations stand on their old footing. Hence, as 12 is to 231, so is $14\frac{1}{2}$ to $281\frac{1}{2}$ the cubic inches in the ale-gallon : but in effect the ale-quart contains 704 cubic inches, on which principle the ale and beer gallon will be 282 cubic inches. The several divisions and multiples of these measures, and their proportions, are exhibited in the tables underneath.

The barrel for ale in London is 32 gallons, and the barrel for beer 36 gallons. In all other places of England, the barrel, both for ale and beer, is 34 gallons.

2.] *Scotch* liquid measure is founded on the pint. The Scotch pint was formerly regulated by a standard jug of cast metal, the custody of which was committed to the borough of Stirling. This jug was supposed to contain 105 cubic inches ; and though, after several careful trials, it has been found to contain only about 103 $\frac{1}{4}$ inches ; yet, in compliance with established custom, founded on that opinion, the pint *scopes* are still regulated to contain 105 inches, and the customary ale measures are about $\frac{1}{4}$ above that standard. It was enacted by James I. of Scotland, that the pint should contain 41 ounces Trone weight of the clear water of Tay, and by James VI. that it should contain 55 Scots Troy ounces of the clear water of Leith. This affords another method of regulating the pint, and also ascertains the ancient standard of the Trone weight. As the water of Tay and Leith are alike, the Trone weight must have been to the Scots Troy weight as 55 to 41 ; and therefore, the pound Trone must have contained about 21 $\frac{1}{4}$ ounces Scots Troy.

4 gills	= 1 mutchkin.
2 mutchkins	= 1 chopin.
2 chopins	= 1 pint.
2 pints	= 1 quart.
4 quarts	= 1 gallon.

* The Scotch quart contains 210 inches ; and is, therefore, about $\frac{1}{10}$ less than the English wine-gallon, and about $\frac{1}{4}$ less than the ale-gallon.

3.] As to the liquid measures of foreign nations, it is to be observed, that their several vessels for wine, vinegar, &c. have also various denominations according to their different sizes and the places wherein they are used. The woaders of Germany, for holding Rhenish and Moselle wines, are different in their gauges ; some containing 14 aumes of Amsterdamm measure, and others more or less. The aume is reckoned at Amsterdam for 8 steckans, or 20 verges, or for $\frac{1}{2}$ of a ton of 2 pipes ; or 4 barrels of French or Bourdeaux, which $\frac{1}{2}$ at this latter place is called *tierçon*, because 3 of them make a pipe or 2 barrels, and 6 the said ton. The steckan is 16 mingles, or 32 pints ; and the verge is, in respect of the said Rhenish and Moselle, and some other sorts of wine, 6 mingles ; but, in measuring brandy, it consists of 6 $\frac{1}{2}$ mingles. The aume is divided into 4 anckers, and the ancker into 2 steckans, or 32 mingles. The ancker is taken sometimes for $\frac{1}{4}$ of a ton, or 4 barrels ; on which footing the Bourdeaux-barrel ought to contain at Amsterdam (when the cask is made according to the just gauge) 124 steckans, or 200 mingles wine and lees ; or 12 steckans, or 192 mingles racked wine ; so that the Bourdeaux-ton of wine contains 50 steckans, or 800 mingles, wine and lees ; and 48 steckans, or 768 mingles of pure wine. The barrels or poignons of Nantes and other places on the river Loire, contain only 12 steckans Amsterdamm measure. The wine-ton of Rochelle, Cognac, Charente, and the Isle of Rhe, differs very little from the ton of Bourdeaux, and consequently from the barrels and pipes. A ton of wine of Chalosse, Bayonne, and the neighbouring places, is reckoned 60 steckans, and the barrel 15, Amsterdamm measure.

The muid of Paris contains 150 quarts, or 300 pints, wine and lees ; or 280 pints clear wine ; of which muids 3 make a ton, and the fractions are

The muid	} containing	36 setiers
The setier		4 quarts
The quart		2 pints
The pint		2 chopins
The chopin		2 demi-setiers
The demi-setier		2 poissons.

The muid is also composed of pipes, or poignons, quarteaux, queves, and demiqueves : those poignons of Paris and Orleans contain about 15 steckans Amsterdamm measure, and ought to weigh with the cask 666 lb. a little more or less. In Provence they reckon by milleroles, and the millerole of Toulon contains 66 Paris pints, or 100 pints of Amsterdamm, nearly ; and the Paris pint is nearly equal to the English wine-quart.

The butts or pipes from Cadiz, Malaga, Alicant, Benecarlo, Saloe, and Mataro, and from the Canaries, from Lisbon, Oporto, and Fayal, are very different in their gauges, though in asfreightments they are all reckoned two to the ton.

Vinegar is measured in the same manner as wine ; but the measures for brandies are different : these spirits from France, Spain, Portugal, &c. are generally shipped in large casks called *pipes*, *butts*, and *pieces* according to the places from whence they are reported, &c. In France, brandy is shipped in casks called *pieces* at Bourdeaux, and *pipes* at Rochelle, Cognac, the ile of Rhé, and other neighbouring places,

per barrel.

IV. Measures of Capacity for things DRY.

1.] *English* dry or corn measure. The standard for measuring corn, salt, coals, and other dry goods, in England, is the Winchester gallon, which contains 272 $\frac{1}{2}$ cubic inches. The bushel contains 8 gallons, or 2178 inches. A cylindrical vessel, 18 $\frac{1}{2}$ inches diameter, and 8 inches deep, is appointed to be used as a bushel in levying the malt-tax. A vessel of these dimensions is rather less than the Winchester bushel of 8 gallons, for it contains only 2150 inches; though probably there was no difference intended. The denominations of dry measure commonly used, are given in the first of the subjoined tables. Four quarters corn make a chaldron, 5 quarters make a wey or load, and 10 quarters make a ton. In measuring sea-coal, 5 pecks

No 198.

make a bushel, 9 bushels make a quarter or vatt, 4 quarters make a chaldron, and 21 chaldrons make a score.

40 feet hewn timber make a load.
50 feet unhewn timber make a load.
32 gallons make a herring barrel.
42 gallons make a salmon barrel.
1 cwt. gun-powder makes a barrel.
256 lb. soap make a barrel.
10 dozen candles make a barrel.
12 barrels make a last.

2.] *Scotch* dry measure. There was formerly only one measure of capacity in Scotland; and some commodities were heaped, others *stroked*, or measured exactly to the capacity of the standard. The method of heaping was afterwards forbidden as unequal, and a larger

Measures. larger measure appointed for such commodities as that custom had been extended to.

The wheat-firiot, used also for rye, pease, beans, falt, and grafs-seeds, contains 21 pints 1 mutchkin, measured by the Stirling jug. The barley-firiot, used also for oats, fruit, and potatoes, contains 31 pints. A different method of regulating the firiot was appointed, from the dimensions of a cylindrical vessel. The diameter for both measures was fixed at 19½ inches, the depth 7½ inches for the wheat-firiot, and 10½ for the barley-firiot. A standard constructed by these measures is rather less than when regulated by the pint; and as it is difficult to make vessels exactly cylindrical, the regulation by the pint has prevailed, and the other method gone into disuse.

If the Stirling jug contain 103½ inches, the wheat-firiot will contain 2109 inches; which is more than 2 per cent. larger than the legal malt-bushel of England, and about 1 per cent. larger than the Winchester bushel: and the barley-firiot will contain 3208 inches. The barley-boll is nearly equal to fix legal malt bushels.

In Stirlingshire, 17 pecks are reckoned to the boll: in Invernesshire, 18 pecks: in Ayrshire, the boll is the same as the English quarter. And the firlots, in many places, are larger than the Linlithgow standard.

3.] *French dry*, are the litron, bushel, minot, mine, septier, muid, and tun. The litron is divided into two demilitrons, and four quarter-litrons, and contains 36 cubic inches of Paris. By ordonnance, the litron is to be three inches and a half high, and three inches 10 lines broad. The litron for falt is larger, and is divided into two halves, four quarters, eight demi-quarters, and 16 mesurettes. The French bushel is different in different jurisdictions. At Paris it is divided into demi-bushels; each demi-bushel into two quarts; the quart into two half-quarts; and the half-quart into two litrons: so that the bushel contains 16 litrons. By ordonnance the Paris bushel is to be eight inches two lines and a half high, and ten inches broad, or in diameter within-side. The minot consists of three bushels, the mine of two minots or six bushels, the septier of two mines or 12 bushels, and the muid of 12 septiers, or an 144 bushels. The bushel of oats is estimated double that of any other grain; so that there go 24 bushels to make the septier, and 288 to make the muid. It is divided into four picotins, the picotin containing two quarts, or four litrons. The bushel for falt is divided into two half-bushels, four quarters, eight half-quarters, and 16 litrons; four bushels make a minot, 16 a septier, and 192 a muid. The bushel for wood is divided into halves, quarters, and half-quarters. Eight bushels make the minot, 16 a mine; 20 mines, or 320 bushels, the muid. For plaister, 12 bushels make a sack, and 36 sacks a muid. For lime, three bushels make a minot, and 48 minots a muid. The minot is by ordonnance to be 11 inches 9 lines high, and 14 inches 8 lines in diameter. The minot is composed of three bushels, or 16 litrons; four minots make a septier, and 48 a muid. The French mine is no real vessel, but an estimation of several others. At Paris the mine contains fix bushels, and 24 make the muid; at Rouen the mine is four bushels; and at Dieppe, 18 mines make a Paris muid. The septier differs in different places: at Paris it contains two mines, or eight bushels, and 12 septiers the

muid. At Rouen the septier contains two mines or 12 bushels. Twelve septiers make a muid at Rouen as well as at Paris; but 12 of the latter are equal to 14 of the former. At Toulon the septier contains a mine and a half; three of which mines make the septier of Paris. The muid or mury of Paris consists of 12 septiers; and is divided into mines, minots, bushels, &c. That for oats is double that for other grain, *i. e.* contains twice the number of bushels. At Orleans the muid is divided into mines, but those mines only contain two Paris septiers and a half. In some places they use the tun in lieu of the muid; particularly at Nantes, where it contains 10 septiers of 16 bushels each, and weighs between 2200 and 2250 pounds. Three of these tuns make 28 Paris septiers. At Rochelle, &c. the tun contains 42 bushels, and weighs two per cent. less than that of Nantes. At Brest it contains 20 bushels, is equal to 10 Paris septiers, and weighs about 2240 pounds. See *TUN*.

4.] *Dutch, Swedish, Polish, Prussian, and Muscovite.*

In these places, they estimate their dry things on the foot of the *last, less, leb, or lecht*; so called according to the various pronunciations of the people who use it. In Holland, the last is equal to 19 Paris septiers, or 38 Bourdeaux bushels, and weighs about 4560 pounds; the last they divide into 27 mudes, and the mude into four scheepels. In Poland, the last is 40 Bourdeaux bushels, and weighs about 4800 Paris pounds. In Prussia, the last is 133 Paris septiers. In Sweden and Muscovy, they measure by the great and little last; the first containing 12 barrels, and the second half as many. See *LAST*. In Muscovy, they likewise use the chefford, which is different in various places: that of Archangel is equal to three Rouen bushels.

5.] *Italian.* At Venice, Leghorn, and Lucca, they estimate their dry things on the foot of the *staro* or *stajo*; the staro of Leghorn weighs 54 pounds: 112 staros and seven-eighths are equal to the Amsterdam last. At Lucca, 119 staros make the last of Amsterdam. The Venetian staro weighs 128 Paris pounds: the staro is divided into four quarters. Thirty-five staros and one-fifth, or 140 quarters and four-fifths, make the last of Amsterdam. At Naples and other parts, they use the *tomolo* or *tomalo*, equal to one-third of the Paris septier. Thirty-six *tomoli* and a half make the *carro*: and a *carro* and a half, or 54 *tomoli*, make the last of Amsterdam. At Palermo, 16 *tomoli* make the *salma*, and four *mondili* the *tomolo*. Ten *salmas* and three-sevenths, or 171 *tomoli* and three-sevenths, make the last of Amsterdam.

6.] *Flemish.* At Antwerp, &c. they measure by the *viertel*; 32 and one-half whereof make 19 Paris septiers. At Hamburg, the *scheepel*; 90 whereof make 19 Paris septiers.

7.] *Spanish and Portuguese.* At Cadiz, Bilbao, and St Sebastian, they use the *fanega*; 23 whereof make the Nantes or Rochelle tun, or nine Paris septiers and a half: though the Bilbao fanega is somewhat larger, inasmuch that 21 fanegas make a Nantes tun. At Seville, &c. they use the *anagoras*, containing a little more than the Paris mine; 36 *anagoras* make 19 Paris septiers. At Bayonne, &c. the *concha*; 30 whereof are equal to nine Paris septiers and an half. At Lisbon, the *alquiver*, a very small measure, 240 whereof make 19 Paris septiers, 60 the Lisbon muid.

Measure. *Measure of Wood for Airing*, is usually the cord; four feet high, and as many broad, and eight long; this is divided into two half-cords, called *ways*, and by the French *membrures*, from the pieces stuck upright to bound them; or *weyes*, as being supposed half a waggon-load.

Measure for Horses, is the hand, which by statute contains four inches.

MEASURE, among botanists. In describing the parts of plants, Tournefort introduced a geometrical scale, which many of his followers have retained. They measured every part of the plant; and the essence of the description consisted in an accurate mensuration of the whole.

As the parts of plants, however, are liable to variation in no circumstance so much as that of dimension, Linnæus very rarely admits any other mensuration than that arising from the respective length and breadth of the parts compared together. In cases that require actual mensuration, the same author recommends, in lieu of Tournefort's artificial scale, the following natural scale of the human body, which he thinks is much more convenient, and equally accurate.

The scale in question consists of 11 degrees, which are as follows: 1. A hair's-breadth, or the diameter of a hair, (*capillus*.) 2. A line, (*linea*), the breadth of the crescent or white appearance at the root of the finger, (not thumb), measured from the skin towards the body of the nail; a line is equal to 12 hair-breadths, and is the 12th part of a Parisian inch. 3. A nail, (*unguis*), the length of a finger-nail; equal to six lines, or half a Parisian inch. 4. A thumb, (*pollex*), the length of the first or outermost joint of the thumb; equal to a Parisian inch. 5. A palm, (*palmus*), the breadth of the palm exclusive of the thumb; equal to three Parisian inches. 6. A span, (*spithama*), the distance between the extremity of the thumb and that of the first finger when extended; equal to seven Parisian inches. 7. A great span, (*dodrans*), the distance between the extremity of the thumb and that of the little finger, when extended; equal to nine inches. 8. A foot, (*pes*), measuring from the elbow to the base of the thumb; equal to 12 Parisian inches. 9. A cubit, (*cubitus*), from the elbow to the extremity of the middle finger; equal to 17 inches. 10. An arm-length, (*brachium*), from the arm-pit to the extremity of the middle-finger; equal to 24 Parisian inches, or two feet. 11. A fathom, (*orgya*), the measure of the human stature; the distance between the extremities of the two middle fingers, when the arms are extended; equal, where greatest, to six feet.

MEASURE is also used to signify the cadence and time observed in poetry, dancing, and music, to render them regular and agreeable.

The different measures or metres in poetry, are the different manners of ordering and combining the quantities, or the long and short syllables. Thus, hexameter, pentameter, iambic, sapphic verses, &c. consist of different measures.

In English verses, the measures are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleases. The most usual are the heroic, generally consisting of five long and

five short syllables; and verses of four feet; and of three feet and a caesura, or single syllable.

The ancients, by variously combining and transposing their quantities, made a vast variety of different measures. Of words, or rather feet of two syllables, they formed a spondee, consisting of two long syllables; a pyrrhic, of two short syllables; a trochee, of a long and a short syllable; and an iambic, of a short and a long syllable.

Of their feet of three syllables they formed a molossus, consisting of three long syllables; a tibrach, of three short syllables; a dactyl, of one long and two short syllables; and an anapest, of two short and one long syllable. The Greek poets contrived 124 different combinations or measures, under as many different names, from feet of two syllables to those of six.

Measure in Music, the interval or space of time which the person who beats time, takes between the raising and falling of his hand or foot, in order to conduct the movement, sometimes quicker, and sometimes slower, according to the kind of music, or the subject that is sung or played.

The measure is that which regulates the time we are to dwell on each note. See **TIME**.

The ordinary or common measure is one second, or 60th part of a minute, which is nearly the space between the beats of the pulse or heart; the systole, or contraction of the heart, answering to the elevation of the hand; and its diastole, or dilatation, to the letting it fall. The measure usually takes up the space that a pendulum of two feet and an half long employs in making a swing or vibration. The measure is regulated according to the different quality or value of the notes in the piece; by which the time that each note is to take up is expressed. The semibreve, for instance, holds one rise, and one fall; and this is called the *measure*, or *whole measure*; sometimes the *measure-note*, or *time-note*; the minim, one rise, or one fall; and the crotchet, half a rise, or half a fall, there being four crotchets in a full measure.

MEASURE Binary or Double, is that wherein the rise and fall of the hand are equal.

MEASURE Ternary or Triple, is that wherein the fall is double to the rise; or where two minims are played during a fall, and but one in the rise. To this purpose, the number 3 is placed at the beginning of the lines, when the measure is intended to be triple; and a C, when the measure is to be common or double. This rising and falling of the hands was called by the Greeks *ἀνακ* and *κατακ*. St Augustine calls it *plausus*, and the Spaniards *compas*. See **ARMS** and **THESES**.

Powder MEASURES in Artillery, are made of copper, and contain from an ounce to 12 pounds: these are very convenient in a siege, when guns or mortars are loaded with loose powder, especially in ricochet firing, &c.

MEASURING, or **MENSURATION**, is the using a certain known measure, and determining thereby the precise extent, quantity, or capacity of any thing.

MEASURING, in the general, makes the practical part of geometry. From the various subjects whereon

Meat.

it is employed, it acquires various names, and constitutes various arts. See GEOMETRY, LEVELLING, TRIGONOMETRY, &c.

MEAT. See FOOD, DIET, DRINK, &c.

Amongst the Jews, several kinds of animals were forbidden to be used as food. The flesh with the blood, and the blood without the flesh, were prohibited; the fat also of sacrificed animals was not to be eaten. Roast meat, boiled meat, and ragouts, were in use amongst the Hebrews, but we meet with no kind of seasoning except salt, bitter herbs, and honey.—They never mingled milk in any ragout or hash, and never eat at the same meal both meat and milk, butter or cheese. The daily provision for Solomon's table was 30 measures of fine wheat flour, 60 of common flour, 20 stalls of oxen, 20 pasture oxen, 100 sheep, besides venison and wild-fowl. See LUXURY.

The principal and most necessary food amongst the ancient Greeks was bread, which they called *αἶσχος*, and produced in a wicker basket called *καστός*. Their loaves were sometimes baked under the ashes, and sometimes in an oven. They also used a sort of bread called *Μαζα*. Barley meal was used amongst the Greeks, which they called *αγρίον*. They had a frequent dish called *ἄσπερον*, which was a composition of rice, cheese, eggs, and honey, wrapped in fig-leaves. The *Μυρραίνιον* was made of cheese, garlic, and eggs, beaten and mixed together. Their bread, and other substitutes for bread, were baked in the form of hollow plates, into which they poured a sauce. Garlic, onions, and figs, seem to have been a very common food amongst the poorer Athenians. The Greeks, especially in the heroic times, ate flesh roasted; boiled meat seldom was used. Fish seems not to have been used for food in the early ages of Greece. The young people only, amongst the Lacedemonians, ate animal food; the men and the old men were supported by a black soup called *μυρραίνιον*, which to people of other nations was always a disagreeable mess. Grass-hoppers and the extremities or tender shoots of trees were frequently eaten by the poor among the Greeks. Eels dressed with beet root was esteemed a delicate dish, and they were fond of the jowl and belly of salt-fish. Neither were they without their sweet-meats: the desert consisted frequently of fruits, almonds, nuts, figs, peaches, &c. In every kind of food we find salt to have been used.

The diet of the first Romans consisted wholly of milk, herbs, and roots, which they cultivated and dressed with their own hands; they also had a kind of gruel, or coarse gross papp, composed of meal and boiling water; this served for bread: And when they began to use bread, they had none for a great while but of unmixed rye. Barley-meal was eaten by them, which they called *Polenta*. When they began to eat animal food, it was esteemed a piece of luxury, and an indulgence not to be justified but by some particular occasion. After animal food had grown into common use, the meat which they most frequently produced upon their tables was pork.

Method of Preserving Flesh-Meat without Spices, and with very little Salt. Jones, in his *Miscellanea Curiosa*, gives us the following description of the Moorish *Eleballe*, which is made of beef, mutton, or camel's flesh, but chiefly beef, and which they cut

Meath.

all in long slices, and let it lie for 24 hours in a pickle. They then remove it out of those jars or tubs into others with water, and when it has lain a night, they take it out, and put it on ropes in the sun and air to dry. When it is thoroughly dried and hard, they cut it into pieces of two or three inches long, and throw it into a pan or caldron, which is ready with boiling oil and fuel sufficient to hold it, where it boils till it be very clear and red when cut. After this they take it out, and set it to drain; and when all is thus done it stands to cool, and jars are prepared to put it up in, pouring upon it the liquor in which it was fried; and as soon as it is thoroughly cold, they stop it up close. It will keep two years; will be hard, and the hardest they look upon to be the best done. This they dish up cold, sometimes fried with eggs and garlic, sometimes stewed, and lemon squeezed on it. It is very good any way, either hot or cold.

MEATH, commonly so called, or otherwise *Eaſt Meath*, to diſtinguiſh it from the county called *West Meath*: A county of Ireland, in the province of Leister, bounded by the counties of Cavan and Louth on the north, the Irish channel on the east, Kildare and Dublin on the south, and West Meath and Longford on the west. It is a fine champaign country, abounding with corn, and well inhabited. It returns 14 members to parliament; and gives title of earl to the family of Brabazon. It contains 326,480 Irish plantation acres, 139 parishes, 12 baronies, and six boroughs; chief town Trim. This district being the most ancient settlement of the Belgians in Ireland, the inhabitants were esteemed the eldest and most honourable tribe: from which seniority their chieftains were elected monarchs of all the Belge; a dignity that was continued in the Hy-n-Faillian without intermission, until the arrival of the Caledonian colonies, under the name of Tuath de Danan, when Conor-Mor, chieftain of these people, obtained, or rather usurped, the monarchical throne, obliged Eochy Failloch, with several of his people, to cross the Shannon, and establish themselves in the present county of Roscommon, where Crothar founded the palace of Atha or Croghan, a circumstance which brought on a long and bloody war between the Belgian and Caledonian races, which was not finally terminated until the close of the 4th century, when the Belgian line was restored in the person of O'Nial the great, and continued until Briam Boromh usurped the monarchical dignity, by deposing Malachy O'Malachlin, about the year 1001. Tuathal Teththomar, by a decree of the Tarah assembly, separated certain large tracts of land from each of the four provinces, where the borders joined together; whence, under the notion of adopting this spot for demaine lands to support the royal household, he formed the county or kingdom of Meath, which afterwards became the peculiar inheritance of the monarchs of Ireland. In each of the portions thus separated from the four provinces, Tuathal caused palaces to be erected, which might adorn them, and commemorate the name in which they had been added to the royal domain. In the tract taken out of Munster, he built the palace called Flachtaga, where the sacred fire, so called, was kindled, and where all the priests and druids annually met on the last day of October; on the evening of which day it was enacted, that no other fire should

be used throughout the kingdom, in order that all the fires might be derived from this, which being lighted up as a fire of sacrifice, their superstition led them to believe would render all the rest propitious and holy; and for this privilege every family was to pay three-pence, by way of acknowledgment to the king of Munster. The second royal palace was erected in the proportion taken out of Connought, and was built for the assembly called the convocation of Vifneach, at which all the inhabitants were summoned to appear on the 1st day of May, to offer sacrifice to *Beal*, or *Bel*, the god of fire, in whose honour two large fires being kindled, the natives used to drive their cattle between them, which was supposed to be a preservative for them against accidents and distempers, and this was called *Beal-Tinne*, or *Bel-Tinne*, or the festival of the god of fire. The king of Connought at this meeting claimed a horse and arms from every lord of a manor or chieftain, as an acknowledgement for the lands taken from that province, to add to the territory of Meath. The third was that which Taittean erected in the part taken from Ulster, where the fair of that name was held, which was remarkable for this particular circumstance, that the inhabitants brought their children thither, males and females, and contracted them in marriage, where the parents having agreed upon articles, the young people were joined accordingly; every couple contracted at this meeting, paid the king of Ulster an ounce of silver by way of acknowledgement. The royal mansion of Tarah, formerly destroyed by fire, being re-built by Tuathal, on the lands originally belonging to the king of Leinster, was reckoned as the fourth of these palaces; but as a fabric of that name had stood there before, we do not find that any acknowledgment was made for it to the king of Leinster.

Meath, with *Clonmacnois*, is a bishop's see, valued in the king's books at L. 373 : 7 : 04, Sterling, by an extent returned anno 28th Elizabeth; but, by a former extent taken anno 30th Henry VIII. the valuation amounts to L. 373, 12s. which being the largest and most profitable for the king, is the measure of the first fruits at this day. This see is reputed to be worth annually L. 3400. There were formerly many Episcopal sees in Meath, as Clonard, Duleek, Kells, Trim, Ardbraccan, Dounaghlin, Slaine, and Foure, besides others of less note; all these, except Duleek and Kells, were consolidated, and their common see was fixed at Clonard, before the year 1152; at which time the divisions of the bishoprics in Ireland was made by John Paparo, cardinal-priest, entitled cardinal of St Lawrence in Damaso, then legate from Pope Eugene III. to the Irish. This division was made in a Synod held on the 6th of March in the abbey of Mellifont, or, as some say, at Kells; and the two sees of Duleek and Kells afterwards submitted to the same fate. The constitution of this diocese is singular, having no dean nor chapter, cathedral, or economy.—Under the bishop, the archdeacon is the head officer, to whom, and to the clergy in general, the *consé d'élire* issued while bishops were elective. The affairs of the diocese are transacted by a synod, in the nature of a chapter, who have a common seal, which is annually lodged in the hands of one of the body, by the ap-

pointment and vote of the majority. The diocese is divided into twelve rural deaneries.

Of Clonmacnois, now annexed to Meath: There is no valuation of this see in the king's books; but it is supposed to be included in the extent of the fee of Meath, taken anno 30th Henry VIII. The chapter of this see consisted anciently of dean, chanter, chancellor, treasurer, archdeacon, and twelve prebendaries, but most of the possessions of them have fallen into lay-hands. At present the deanery is the only part of the chapter which subsists, to which the prebend of Cloughran is annexed, and he hath a seal of office, which appears to have been the ancient Episcopal seal of this see. This fee was founded by St Kiaran, or Ciaran, the younger, in 543 or 549; and Dermody, the son of Ceronill, king of Ireland, granted the site on which the church was built.

West Meath. See WESTMEATH.

MEATUS AUDITORIUS. See ANATOMY, n^o 139.

MEAUX, an ancient town of France, in Brie, with a bishop's see, seated in a place abounding in corn and cattle, on the river Marne, which divides it into two parts, and its trade consists in corn, wool, and cheese. E. Long. 2. 58. N. Lat. 48. 58.

MECENAS, or MECENAS (C. Cilnius), a celebrated Roman knight, descended from the kings of Etruria. He has rendered himself immortal by his liberal patronage of learned men and of letters; and to his prudence and advice Augustus acknowledged himself indebted for the security he enjoyed. His fondness for pleasure removed him from the reach of ambition; and he preferred dying, as he was born, a Roman knight, to all the honours and dignities which either the friendship of Augustus or his own popularity could heap upon him. To the interference of Mecenas, Virgil owed the retribution of his lands; and Horace was proud to boast that his learned friend had obtained his forgiveness from the emperor, for joining the cause of Brutus at the battle of Philippi. Mecenas was himself fond of literature; and, according to the most received opinion, he wrote a history of animals, a journal of the life of Augustus, a treatise on the different natures and kinds of precious stones, besides the two tragedies of Octavia and Prometheus, and other things, all now lost. He died eight years before Christ; and on his death-bed he particularly recommended his poetical friend Horace to the care and confidence of Augustus. Seneca, who has liberally commended the genius and abilities of Mecenas, has not withheld his censure from his dissipation, indolence, and effeminate luxury. From the patronage and encouragement which the princes of heroic and lyric poetry among the Latins received from the favourite of Augustus, all patrons of literature have ever since been called *Mecenates*. Virgil dedicated to him his Georgics, and Horace his odes.

MECCA, an ancient and very famous town of Asia, in Arabia the Happy; seated on a barren spot, in a valley surrounded with little hills, about a day's journey from the Red-Sea. It is a place of no strength, having neither walls, nor gates, and the buildings are very mean. That which supports it is the resort of a great many thousand pilgrims annually, for the shops are scarcely open all the year besides. The inhabitants

Meath
Mecca.

Mecca.

are poor, very thin, lean, and swarthy. The hills about the town are very numerous; and consist of a blackish rock, some of them half a mile in circumference. On the top of one of them is a cave, where they pretend Mahomet usually retired to perform his devotions, and hither they affirm the greatest part of the Alcoran was brought him by the angel Gabriel. The town has plenty of water, and yet little garden-stuff; but there are several sorts of good fruits to be had, such as grapes, melons, water-melons, and cucumbers. There are also plenty of sheep brought thither to be sold to the pilgrims. It stands in a very hot climate; and the inhabitants usually sleep on the tops of their houses for the sake of coolness. In order to protect themselves from the heat through the day, they carefully shut the windows, and water the streets to refresh the air. There have been instances of persons suffocated in the middle of the town by the burning wind called *Simoom*.

As a great number of the people of distinction in the province of Hedsjas stay in the city, it is better built than any other in Arabia. Amongst the beautiful edifices it contains, the most remarkable is the famous *Kaba*, or *Caaba*, "The house of God," which was held in great veneration by the Arabs even before Mahomet's time.

No Christian dare go to Mecca; not that the approach to it is prohibited by any express law, or that the sensible part of the Mahometans have any thing to object to it; but on account of the prejudices of the people, who, regarding this ground as sacred, think Christians unworthy of setting their foot on it; it would be profaned, in the opinion of the superstitious, if it was trod upon by infidels. The people even believe, that Christians are prevented from approaching by some supernatural power; and they tell the story of an infidel, who having got so far as the hills that surround Mecca, all the dogs of the city came out, and fell upon him; and who, being struck with this miracle, and the august appearance of the Kaba, immediately became a Mussulman. It is therefore to be presumed, that all the Europeans who describe Mecca as eye-witnesses, have been renegades escaped from Turkey. A recent example confirms this supposition. On the promise of being allowed to preserve his religion, a French surgeon was prevailed on to accompany the Emir Hadjsi to Mecca, in quality of physician; but at the very first station, he was forced to submit to circumcision, and then he was permitted to continue his journey.

Although the Mahometans do not allow Europeans to go to Mecca, they do not refuse to give them descriptions of the Kaba, and information with regard to that building; and there are persons who gain their bread by making designs and little pictures of the Kaba, and selling them to pilgrims. See *CAABA*.

The Mahometans have so high an opinion of the sanctity of Mecca, that they extend it to the places in the neighbourhood. The territory of that city is held sacred to certain distances, which are indicated by particular marks. Every caravan finds in its road a similar mark, which gives notice to the pilgrims when they are to put on the modest garb in which they must appear in those sacred regions. Every Mussulman is obliged to go once in his life, at least, to Mecca, to

perform his devotions there. If that law was rigorously enforced, the concourse of pilgrims would be prodigious, and the city would never be able to contain the multitudes from all the countries where the Mahometan religion prevails. We must, therefore, suppose, that devotees alone perform this duty, and that the others can easily dispense with it. Those whose circumstances do not permit a long absence, have the liberty of going to Mecca by a substitute.—A hired pilgrim, however, cannot go for more than one person at a time; and he must, to prevent frauds, bring an attestation in proper form, from an Imam of Mecca, that he has performed the requisite devotions on behalf of such a person, either alive or dead; for, after the decease of a person who has not obeyed the law during his life, he is still obliged to perform the journey by proxy.

The caravans, which are not numerous, when we consider the immense multitude of the faithful, are composed of many people who do not make the journey for purposes of devotion. These are merchant, who think they can transport their merchandizes with more safety, and dispose of them more easily; and contractors of every kind, who furnish the pilgrims, and the foldiers who escort the caravans, with necessities. Thus it happens, that many people have gone often to Mecca, solely from views of interest. The most considerable of those caravans is that of Syria, commanded by the Pacha of Damascus. It joins at some distance the second from Egypt, which is conducted by a Bey, who takes the title of Emir Hadjsi. One comes from Yemen, and another, less numerous, from the country of Lachsa. Some scattered pilgrims arrive by the Red Sea from the Indies, and from the Arabian establishments on the coasts of Africa. The Perians come in that which departs from Bagdad; the place of conductor to this last is bestowed by the Pacha, and is very lucrative, for he receives the ransoms of the heretical Perians.

It is of consequence to a pilgrim to arrive early at the holy places. Without having been present from the beginning at all the ceremonies, and without having performed every particular act of devotion, a man cannot acquire the title of Hadjsi: this is an honour very much coveted by the Turks, for it confers real advantages, and makes those who attain it to be much respected. Its infrequency, however, in the Mahometan dominions, shows how much the observation of the law commanding pilgrimages is neglected. A similar custom prevails among the Oriental Christians, who are also exceedingly emulous of the title of Hadjsi, or Mokdasi, which is given to pilgrims of their communion. In order to acquire this title, it is not sufficient that the person has made the journey to Jerusalem; he must also have kept the passover in that city, and have assisted at all the ceremonies of the holy weeks.

After all the essential ceremonies are over, the pilgrims next morning move to a place where they say Abraham went to offer up his son Isaac, which is about two or three miles from Mecca: here they pitch their tents, and then throw seven small stones against a little square stone building. This, as they affirm, is performed in defiance of the devil. Every one then purchases a sheep, which is brought for that purpose, eating

Mecca.

Mecca,
mechanics

eating some of it themselves, and giving the rest to the poor people who attend upon that occasion. Indeed these are miserable objects, and such starved creatures, that they seem ready to devour each other. After all, one would imagine that this was a very sanctified place; and yet a renegade who went in pilgrimage thither, affirms there is as much debauchery practised here as in any part of the Turkish dominions. It is 25 miles from Jodda, the sea-port town of Mecca, and 220 south-east of Medina. E. Long. 40. 55. N. Lat. 21. 45.

MECHANICAL, an epithet applied to whatever relates to mechanics: thus we say, mechanical powers, causes, &c. See the articles **POWER**, **CAUSE**, &c.

The mechanical philosophy is the same with what is otherwise called *corpuscular philosophy*. See **CORPUSCULAR**.

This manner of reasoning is much used in medicine; and, according to Dr Quincy, is the result of a thorough acquaintance with the structure of animal bodies: for considering an animal body as a composition out of the same manner from which all other bodies are formed, and to have all those properties which concern a physician's regard, only by virtue of its peculiar construction; it naturally leads a person to consider the several parts, according to their figures, contexture,

and use, either as wheels, pulleys, wedges, levers, screws, cords, canals, strainers, &c. For which purpose, continues he, it is frequently found helpful to design in diagrams, whatsoever of that kind is under consideration, as is customary in geometrical demonstrations.

For the application of this doctrine to the human body, see the article **MEDICINE**.

MECHANICAL, in mathematics, denotes a construction of some problem, by the assistance of instruments, as the duplicature of the cube and quadrature of the circle, in contradistinction to that which is done in an accurate and geometrical manner.

MECHANICAL CURVE, is a curve, according to Descartes, which cannot be defined by any algebraic equation; and so stands contradistinguished from algebraic or geometrical curves.

Leibnitz and others call these mechanical curves *transcendental*, and dissent from Descartes, in excluding them out of geometry. Leibnitz found a new kind of transcendental equations, whereby these curves are defined: but they do not continue constantly the same in all points of the curve, as algebraic ones do. See the article **TRANSCENDENTAL**.

Mecca,
Mechanics.

M E C H A N I C S,

IN the strict sense of the word, denotes the method of constructing machines to be set in motion, and to answer some useful purposes, by certain powers, either natural or artificial. According to this definition, the nature of the powers themselves is not the object of mechanical investigation, but rather the effect of them upon the passive bodies which we call *machines*; and the constructing of these in such a manner, that the powers may act upon them with the least possible obstruction, and produce the intended effect to the greatest advantage, is the perfection of **MECHANICS**.

It is usual, in treatises upon this subject, to begin with an investigation of the properties of *matter* itself, and of *central forces*; but the former is not to be investigated by mechanical means, and the latter belong so much to astronomy, that very little needs to be said upon them in this place; for which reason we refer to the articles **ASTRONOMY**, **MATTER**, and **MOTION**, for a discussion of these subjects. In treating of mechanics, therefore, we shall begin with a description of what are commonly called the *mechanic powers*; and afterwards consider the various ways in which they may be modified, in order to produce the effects expected from them.

SECT. I. Of Material or Mechanical Power in general.

§ 1. Production of Motion and Rest.

IN mechanics every thing is called a power which is capable of acting upon a solid body; and every power which can act upon matter is supposed to be material, without regarding any abstruse speculations concern-

ing its nature. Hence the force of gravity, of electricity, of fire, of air, of water, the power of animals, of bodies pressing or impinging with violence upon one another, are all accounted mechanical powers when applied to set machines in motion.

As any single power, when applied to a material body, will set it in motion in proportion to its quantity, so the action of an opposite power upon the same body produces rest. This may be easily conceived; for supposing two men to pull a log of wood with equal degrees of strength in directions exactly opposite to one another, the log will remain immovable. In like manner, if we put in a weight into one scale of a balance, motion will be produced; but rest is the certain consequence of counterpoising it with an equal weight in the opposite scale. When a weight is suspended freely in the air, we are apt to imagine that it is acted upon by no force whatever; but we will soon discover our mistake, by withdrawing the pressure of the air from one side; for the body then, instead of remaining at rest, will move with great violence to one side, and even contrary to the direction of gravity itself, unless it be extremely heavy. Whether rest be in all cases produced by the action of opposite powers upon the same substance, is a speculation to be discussed under the article **MOTION**.

§ 2. Of Resistance.

WHEN any moving power is stopped by a fixed obstacle, so that it can proceed no farther, we say that it is *resisted* by that obstacle. In this case we are apt to imagine that there is no force exerted by the resisting obstacle; but it is found by experience, that resistance is to all intents and purposes equivalent to a

Ultimate
causes of res-
istance.

Mechanical
Power.

power equal and contrary to that which is impelled against the resisting obstacle. This is exemplified in the case of a man standing in a boat, and pushing with a pole against the bank of a river or lake. In this case every one knows that the boat will go off in a direction contrary to that in which he pushes; but if the boat be fastened by means of a hook and rope to that part of the pole which is between the man's body and the bank, the boat will remain immovable by reason of the equality betwixt the action of the man upon the pole forward, and of the boat upon the same pole backward. Thus, in fig. 1. when the man pushes with the pole C against the bank D, in the direction CA, the boat B will be carried away from the bank in the direction AC; but if, by means of the rope E, the boat be fastened to the pole AC, the recoil of the boat in the direction AC will be just equal to the push given by the man in the direction CA, so that no motion will ensue let him exert ever so much strength. Hence we see, that by means of a resisting obstacle a power may be made to counteract itself, so that a motion or tendency to it may be produced in any direction; and in this case, as well as in the former, rest is produced by the opposition of two contrary forces.

Mate
CCLXXXII.

The very same effect would follow, though we should suppose the man in the boat not to push against the bank or any fixed obstacle, but against another boat fastened by means of a rope to his own. In this case both the boats will recede from each other till the rope be stretched; after which they will both remain immovable, unless they be acted upon by some power external to both. If both boats be at liberty, they will mutually recede from each other till they get beyond the reach of the pole.

Resistance
equivalent
to an oppos-
ing power.

Resistance, whatever we may speculate about it, seems ultimately to depend on the power of gravity joined with that of cohesion. Thus a weight of 100 pounds, even when suspended in the freest manner we can imagine, will resist much more than 20 pounds suspended in the same manner; and though hard bodies resist to a great degree, yet unless connected with some very heavy body, they are easily moved out of their place; and the immense gravitation of the whole globe of earth, we may justly suppose to be the source of all resistance whatever to mechanical powers.

On the whole, therefore, we may consider resistance as an active power; but the action of which is confined to a very limited space, or to the single point of contact; though several experiments tend to show, that even before actual contact bodies show a very perceptible degree of resistance.

§ 3. Of the Communication of Power.

This depends entirely upon that property of bodies which is called their *attraction of cohesion*, and the immobility of their particles among themselves; for if the parts of a body are absolutely moveable among themselves, they can neither communicate motion by impulse nor by pressure. The most common method of communicating motion in the mechanical way is by pressure, which is generally accomplished by means of the six mechanical powers to be afterwards described: collision being employed only in certain particular

cases, the most remarkable of which will be pointed out under the article *MOTION*.

Mechanical
Power.

The motion, which by means of an hard inflexible body is communicated to any other, may be confined to a single point, or it may be diffused over any assignable space. Thus, in fig. 2. let us suppose that any assignable power is applied to the point E, urging it from E towards D; the whole of that force will rest upon the point of contact betwixt the ball C and the line BD. The weight, if placed exactly perpendicular to the horizon, will remain upright, without inclining either to one side or other; for the power of resistance in the line BD is exactly equal to the impulse of the weight lying upon E; so that it is in the same situation with the man and boat in the first example, when he had the boat hooked to the pole with which he pushed against the bank. If instead of opposing the end of the resisting body BD to the ball C, we place them in the position represented in fig. 3. then the whole of the power will rest upon any point of the line BD we please. For if we suppose the line EC to drive the line BD before it in the position represented in the figure, it is plain that the whole force of that line will be discharged for a moment upon the line F, or upon any obstacle we choose to put in its way in another part of the line; but if we place two supports or resistances to the moving line BD, as F and G in fig. 4. it is equally plain, that one half of the power will rest upon the one and one half upon the other. For the whole force urging forward the line BD is but a certain and determined quantity; and if divided betwixt two obstacles, each of these must undoubtedly bear one half. In like manner, if, as in fig. 5. the power be opposed by four obstacles, each of them will bear only one-fourth part; and so on if we suppose it opposed by ever so many. For reasons afterwards to be assigned, however, it is absolutely necessary that the force on E act in a line directly perpendicular upon BD; that the obstacles be all at equal distances, comparatively speaking, from C; as H and I, F and G, &c. likewise that they be of exactly the same height; for thus only the pressures, and consequently the motion, can be made uniform in all parts. On this principle depends in a great measure the perfection of printing presses, oil presses, and all other machines intended to produce a violent and uniform pressure upon any broad and flat surface.

As the pressure upon a single point may thus be diffused over a broad surface, so may that upon a broad surface be concentrated upon a single point or a surface of small dimension, as in fig. 6. Here it is plain that whatever pressure is applied to the line AB, or any part of it in a perpendicular direction, must be sustained by the point D; for if there was no resistance, this point would be driven along with the line AB, and the moment it was stopped the power which urged it on must likewise be stopped. It is true, that unless the power act directly perpendicular to the point D, or the line CD be supported that it cannot move either to one side or to another, the impulse will be but momentary; but of this we shall treat at large in the subsequent part of this article. On the principle just mentioned depends in a great degree the force of gimlets, augers, boring gimlets, &c.

MECHANICS.

Atwell, Prin. & Co. Sculptors, fecit.

§ 4. Of changing the Direction of a Power into one directly opposite.

THIS in all cases is only to be accomplished by the application of a power greater than that of which we wish to change the direction. Thus, in fig. 2. suppose we wish to change the direction of the power at E from the direction AC to that of CA, we will find it impossible to do so by any other means than the application of a greater power from D towards C. If the two powers are equal, there will be no motion whatever; and the degree of motion produced at last will only be the difference betwixt the two powers. If it be wanted therefore to produce a power in the direction CA, equal and opposite to that in the direction AC, one must be applied in the direction CA double to the former. This principle is different from that first mentioned, in which motion is produced by pushing against a fixed obstacle while the moving power is not resisted on the opposite side; for here the power of gravity, or whatever we suppose to act upon E, resists according to its quantity, and the whole is in the situation of the boat when hooked to the pole fig. 1. To produce motion, therefore, a new force must be applied, as if a person was to push from the bank D against the hooked pole of the boat in that figure. The principle just now laid down does not militate against the apparent ascent of bodies by the action of gravity, or the repulsion of elastic balls from one another by what is called the power of elasticity. In both cases a greater power is applied than the simple force of gravity, and with the excess of this power the body ascends, as shall be afterwards shown.

§ 5. Of the Motion produced by two or more Powers acting upon a Body in directions oblique to each other.

As the action of two powers in direct opposition to each other is attended with the destruction of both if the powers are equal, and of one of them if they are unequal; so the action of powers directed obliquely upon one another is productive of motions in various directions, according to that of the acting powers.

The motion produced by the action of two powers is always in the diagonal of the parallelogram expressed by these powers. Thus, in fig. 7. let the body A be acted upon at once by two forces, one of which would carry it from A to B in the same time that the other would carry it from A to C. The body will then describe AD, the diagonal of a square, in the time that it would have described one of the sides by a single power applied to it. This is in consequence of its obeying both forces; as it is evident that it has moved as far as from A to B, and likewise from A to C, which is precisely the effect that the two powers would have had upon it separately. In this case the body has acquired a greater power than it would have had from a single power, but less than it would have acquired from the union of the two powers if they had acted directly in concert with each other; because the diagonal of a square is less than the sum of the sides, and the power with which any body moves is exactly proportioned to its velocity. If, instead of supposing the forces equal, we suppose one of them considerably greater than the other, then the greater force

will carry the body farther in its own direction than the other, and the whole will be represented by a parallelogram, as in fig. 8. In this case it is evident that the body has moved exactly in conformity to the direction of both powers, viz. the whole length of AB, and the whole length of AC. In this case also the loss of motion is less than in the former; because the length of the oblong parallelogram approaches much nearer to the sum of the sides than the diagonal of a square; and the greater inequality there is betwixt the sides, the less power is lost.

If, instead of acting at right angles to each other, the direction of the powers forms an acute angle, as in figs. 9, 10, 11, the power produced will be considerably greater than either of the original ones; and the more acute the angle is, the greater will be the augmentation, as is evident from an inspection of the figures. The reason of this, though not quite so obvious, is the same with the former. Thus the body A in fig. 9. had it been acted upon by only one power, viz. that denoted by AB, would have been at B, or carried as far forward as E, the half of the diagonal; its oblique direction upward not being taken into the account. Had it been acted upon by the force AC alone, it would have been at C with an obliquity as far down as the other is up. As these obliquities, however, are in contrary directions, they must of necessity destroy one another; and therefore the body moves neither to one side nor another, but proceeds with the sum of the direct forces of the powers, or those by which they move in the straight diagonal. But either of the two powers would have brought it forward as far as E; of consequence both conjoined must carry it on to D, the whole length of the diagonal. Thus it appears, that when a body is acted upon by two powers which partly conspire together, the power produced will be the exact sum of them as far as they do conspire, and the loss arises entirely from the opposition betwixt them; for all powers which do not directly conspire, oppose one another in a certain degree. Hence when the acting forces make an obtuse angle with each other, as in figs. 12, 13, there is then a very great loss of power, because there is such an opposition betwixt them; and it is only that small part of their motion which acts in concert that can produce any in the body acted upon; but this, as in the former case, is exactly double to what it would be if only one of them acted upon the body. Thus, in fig. 12. the whole direction of the powers from E to B, and from B to C, is in absolute opposition to each other; and therefore, supposing them equal, must be totally lost. In the direction AD they conspire; and therefore the body will move twice as far in that direction as is expressed by that of the lines in the figure; that is, from A to D, instead of only from A to E, which is the limit of each of the forces. In cases of this kind, the more obtuse the angle is at which the forces act, the greater is the loss of power, as is evident from an inspection of figs. 12, 13.

Some who are but beginning to the study of mechanics may be embarrassed in their ideas how two forces acting at right angles to each other can in any manner of way oppose each other, as in fig. 7.; as we find that a body descending by the force of gravity

Plates'

Mechanical
Power.
Plate
CCLXXXIII.

may be pushed to a side seemingly by the least force imaginable. But this will easily be understood from fig. 14. which is only a square turned into another position. Here it is plain that the powers AB and AC oppose each other as much as they conspire; that is in the proportion of half the diagonal of the square: this quantity therefore is totally lost, and the body proceeds with the other half; which being doubled on account of each of the powers proceeding with one half of the diagonal, gives the whole diagonal for the total motion produced.

5
Ultimate
cause of
this shown

But however plain this may appear from an inspection of the figure, it is by no means so apparent when we come to try it by numbers. Thus, supposing each of the sides AB and AC to be 5, the diagonal of the square will be nearly 7.071; but if from the sum of the sides 10 we take this number, or half of it from each number, we will have only 2.919 for the whole motion, instead of the diagonal 7.071 which is the reality. From an inspection of the figure also we plainly see, that if one diagonal is gained by the powers conspiring together or acting in concert, another is lost by their opposition. It is natural therefore to inquire, How can any two powers gain or lose more than their own quantity; for the two powers taken together amount but to ten, but the two diagonals, one of which is gained and the other lost, amount between them to upwards of fourteen? To solve this seeming paradox, we must consider, that as the diagonal of the square ABCD, fig. 14. is generated from the two sides AB and CD, so these sides themselves may be accounted the diagonals of two other smaller squares ABE and AEC, fig. 15. each of the sides of which is half the diagonal of the large one. From the sum of the sides of these squares, which to the large square are the source of power, it is evident that a diagonal may be taken and another remain, because each of the sides is half a diagonal.

6
All powers
are com-
pounded of
others.

Hence we not only see that every mechanical power we are acquainted with may be derived from two others, but have a demonstration that it *actually is so*; not only because this supposition explains the phenomena, but because we are involved in an inexplicable contradiction if we suppose any thing else, for no power can lose more than its own quantity; and if it loses more than one half, it can never produce effects equivalent to another half; which we see must be the case, if we suppose any two unoriginated powers acting upon one another at right angles, or indeed any other way, though the supposition of their acting at right angles makes the matter more plain than any other. This leads to a very curious speculation concerning the origin of mechanical motion, of which an account is given under the article MOTION.

7
Experiment
illustrating
the truth of
this doc-
trine.

Hitherto we have considered both the powers not only as equal at the beginning, but as continuing so throughout their whole course: but this is a supposition which scarcely exists in nature, unless the powers are kept from exerting themselves otherwise than by simple pressure. Thus, in fig. 16. supposing the body A pulled in the direction AB by the weight D of five pounds put over the fixed pin B, and pulled in the direction AC by C, another weight of five pounds fastened to it by a string; the whole will be kept in the position represented in the figure by a weight of

7.071 pounds fastened to it by a string, and put over the pin F, situated any where in the diagonal line FAG; and let us add ever so much weight, provided it be done to D and C in the proportion of five, and to E in that of 7.071, the body A will remain suspended in the air without altering its position in the least.

If, instead of making the weights equal, we make one exceed the other in any proportion, the weight necessary to counteract them will never be required equal to both, but will always be in proportion to the diagonal of the parallelogram of which the weights represent the sides. Thus, in fig. 17. if we suppose the body A pulled in the direction AB by the weight G of four pounds, and in the direction AC by the weight H of three pounds, it will be kept suspended by the weight F of five pounds put over the pin E, placed any where in the diagonal line EAD. For the diagonal AD is equal (by Prop. 47. Book 1. of Euclid) to the square-root of the sum of the squares of the sides AB and AC, or CD and BD. But the square of AB is $4 \times 4 = 16$ pounds, and that of AC is $3 \times 3 = 9$ pounds by the supposition; and $16 + 9 = 25$, the square-root of which is 5; and these proportions will be found to hold invariably in whatever way we apply mechanical powers; though, when they act at oblique angles, the diagonals must be calculated by other methods.

If, however, we set any of the powers at liberty, we shall find that none of them will continue the same even for a moment. If we suppose any of them to be the power of gravity, which is the most constant and equable we are acquainted with, this is found to increase prodigiously; and, on the other hand, if we suppose one of them to be a projectile force, as of a stone thrown by the hand, we will find in like manner, that it will be diminished to a great degree in a very little time. In all cases, however, where a body is acted upon by two forces either increasing or decreasing, unless both increase or decrease exactly in proportion to their original quantity, the body acted upon will describe a curve. Thus, in fig. 18. suppose the body A to be acted upon by two equal powers AB and AC; at the end of the first moment it will be at *d*, the end of the diagonal of the small square *Abcd*; but if now the force AC be increased to double what it was in the preceding moment, the body will at the end of the second moment be at *g*, the extremity of the parallelogram *dgfg*; and by another increment of the same power, will be at the end of the third moment at *k*, and so on. This is similar to the motion of falling bodies, of which we shall treat hereafter; but if one of the powers diminishes instead of increasing, the phenomena will be different. Thus, in fig. 19. supposing the body at A to be actuated the first moment by the two forces AB and AC; at the end of that moment it will be at the extremity of the diagonal AD; but next moment, supposing the power AC to be diminished one half, the other remaining the same, it will then be at *g*, and the third moment at *k*, thus describing another kind of curve. If, while one of the powers decreases the other increases, a third kind of curve will be generated; and by proper management of these powers, the body may be made to describe the segment of a circle, as in fig. 20; where

duced.

Mechanical Power. where it is manifest that one power continually decreases while the other increases.

Machine for showing the action of oblique powers. Fig. 21. The following machine has been contrived to illustrate the operation of oblique powers upon each other. ABCD is a wooden square, so contrived that the part BEFC may draw out from it or be pushed back at pleasure. To this is joined a pulley H, freely moving upon its axis, which will be at H when the piece is pushed in, and at *b* when it is drawn out. To this part let the ends of a straight wire *k* be fixed, so as to move along with it under the pulley; and let the ball G be made to slide easily upon the wire. A thread *m* is fixed to this ball, and goes over the pulley to I; by which means the ball may be drawn up on the wire parallel to the side AD, when the part BEFC is pushed as far as it will go into the square: but when this part is drawn out, the ball must be carried along with it parallel to the bottom of the square DC. Thus the ball may be drawn either perpendicularly upward by pulling the thread *m*, or moved horizontally by pulling out the part BEFC, in equal times and through equal spaces, each power acting equally and separately upon it. But if, when the ball is at G, the upper end of the thread be tied to the pin I, in the corner A of the fixed square, and the moveable part BEFG be drawn out, the ball will then be acted upon by both the powers together: for it will be drawn up by the thread towards the top of the square, and at the same time carried with its wire *k* towards the right hand BC, moving all the while in the diagonal line L, and will be found at *g* when the sliding part is drawn out as far as it was before; which then will have caused the thread to draw up the ball to the top of the inside of the square, just as high as it was before when drawn up singly by the thread without moving the sliding part.

To Of bodies acted upon by three forces. If a body is acted upon by three forces, the investigation becomes somewhat more complex, though it is still easily explained on the foregoing principles. Thus, in fig. 22. let the body A be pulled sidewise in opposite directions by the two equal weights GG put over the pins B and C, and directly downward by the weight H, the same with G. In this case it is plain, that each of the weights G and C sustain one half of the weight H; and as both taken together are double in quantity to H, it might be supposed that they would be abundantly able to keep the body A in its position. The case, however, is very different. As each of the weights G sustains only one half of H, it follows that H acts only with one half of its weight upon them. The body A, therefore, is pulled in the direction AC and AB by two powers, each of which is as 2, and in the direction AF by two, which are only as one. With the force AB, therefore, were it to act upon it singly, it would describe the diagonal AD, and with that AC it would describe the diagonal AE. These two diagonals are in truth the forces by which it is now actuated, and the effect is precisely according to the principles already laid down. By each of them taken separately, the body would be brought down to F; their lateral action being in opposite directions destroys itself; and by their conjunct action, the body would be brought down to double the space AF, that is to H, and consequently would describe the diagonal of the small square ADHE; which diagonal is

equal to the side of the large one, and the very same that the body would have described though the two lateral weights had not been present.

Hence it appears, that though we pull a body ever so strongly by strings in a direction opposite to each other, it will still require an equal weight to retain it in equilibrium; that is, supposing the strings to be perfectly flexible. There may indeed be a deception in making an experiment of this kind; for the body will never descend as far as H, nor near that distance; but then it must be observed, that when the strings begin to bend in the middle, the weights GG act in a direction different from what they did originally, and pull the body upwards instead of laterally; in which case, it must either remain at rest, as in fig. 23. or move upwards, as in fig. 24.

When the powers act in the direction AB and AC, fig. 23. one half of the weight H is sustained by each of them. The body is therefore pulled in the directions AB and AC by two powers, each of which is as 2; and in the direction AF by other two, each of which is as 1. By the power AB it would be made to move in the diagonal AD of the parallelogram ABDF; and by the power AC, in the diagonal AE of the parallelogram ACEF; but these diagonals are equal and contrary to each other, and therefore destroy each other; of consequence the body remains at rest.

In fig. 24. the body A with the weight H appended to it is placed nearer to the point B than to C by one-third. Of consequence, as will afterwards be explained, it bears two-thirds of the weight H, while C sustains only one-third. The acting powers, therefore, are now the diagonals of two unequal parallelograms. One power draws the body in the direction AB with a force as 3, while the weight H draws it in the direction AH with a force as 2. By it, therefore, the body would be drawn in the direction of the diagonal AD of the parallelogram BDEA. On the other hand, it is acted upon by the power AC, which is likewise as 3, while the weight H draws it down with a force only as 1. By this, therefore, it would be drawn in the direction of the line AG, the diagonal of the parallelogram ACGF. We must now make these two diagonals the sides of a third parallelogram ADIG; and in the diagonal AI of this parallelogram it will go, for the reasons already given.

If four or more forces act upon a body in different directions, the case becomes very complicated; and if acted upon many powers be employed, it will by no means be easy by four or more forces to determine *a priori* which way the body will tend. Cases of this kind, however, seldom occur in practical mechanics; and when they do, it will be better to determine them by actual experiment than by a tedious investigation, which, after all, may be liable to a mistake. We forbear, therefore, to give more examples; though, if the reader inclines to exercise his ingenuity, he must proceed upon the plan already laid down, viz. by combining the different powers together; forming diagonals from these parallelograms; combining these diagonals into a third set of parallelograms; and the diagonals thence resulting into a fourth set, &c. until at last a single one is met with prevailing over all the rest, or two destroying each other. If one prevails, the

Mechanical
Power.

body will move in that direction; but if two destroy each other, the body will remain at rest.—It must also be observed, that in making drawings of this kind, the longest line always represents the greatest power, and that without a single exception to the contrary. By mere mechanical construction, therefore, with scale and compass, we may be able to ascertain the direction of oblique powers to as great accuracy as we can ever have occasion for in practice.

12
Of the various ways in which powers may be produced.

We shall conclude this subject with observing, that as every power certainly is produced by the action of two others, so it may be by innumerable others. Thus, in fig. 25. the power AD may be produced by the two sides of the square ABCD; by the sides of the oblique-angled parallelogram AaDb, of the smaller parallelogram AdDd; or of the large parallelogram AE, DF, &c. Hence it is easy to produce any power, whether strong or weak, from the action of any two powers whose direction we have at our command, without regard to their quantity. If we make the generating powers conspire together, a strong one will be produced; or if they oppose each other to a certain degree, they will produce a weak one. The strongest that can be produced by any two powers is when they act the same way in a direct line.

§ 6. Of the Relation betwixt Velocity and Power.

HITHERTO we have supposed the bodies to be moved not to make any resistance to motion in any direction, unless opposed by a fixed obstacle; in which case, velocity and power would be the same thing; and thus it always appears to be when we represent powers by lines upon paper. But when we come to practice, matters turn out very different. A ball of cork moving with any degree of velocity will not have an equal power with one of wood moving with the same velocity; neither will a wooden ball have the same power with a metallic one. Among the metals themselves, too, there is a difference; for the lighter metals are inferior in power to the heavier ones. Gravity, therefore, must be accounted the power which gives to moving bodies what we call their force or momentum; for according to the weight of a body, so will its impulse always be, and that whether it moves upwards, downwards, sidewise, or in a circle. The absolute power of a body, therefore, must be measured by comparing the gravity of different bodies together, and denoting one of them by unity; making the other 2, 3, 4, &c. according as it is twice, thrice, or four times, the specific gravity of the former. Thus let an hollow ball of metal be filled with water; if the ball be very thin, we may let its weight pass unnoticed, or we may make allowance for it in the calculation. Supposing the weight of this ball then to be 1, if it moves with a velocity of 10 feet in a second, its absolute force or momentum will be $10 \times 1 = 10$; a ball of stone of equal size which weighs three times as much as the former, if moved with an equal velocity, will have a force of $10 \times 3 = 30$; a ball of tin which weighs 7 times as much, will have a momentum of 70; and a ball of gold or platinum would have a momentum of 190 or 200.

This will also hold exactly, by increasing the quantity of matter, where it is deficient in specific gravity. Thus, if the hollow metallic ball be increased in dia-

meter, so that it shall equal in weight the ball of stone or metal, it will have the very same force with that ball; and in like manner, it might be made to have a momentum equal to the metallic balls, though not without a very considerable increase of size.—Great Mr Atwood's observation is, that the place of wood's observation is, that the battering-rams used by the ancients were no less efficient in beating down the walls of cities than the modern artillery. "The battering-rams of the ancients (says he) consisted of very large beams of wood terminated by solid bodies of brass or iron; such a mass being suspended as a pendulum, and driven partly by its gravity and partly by the force of men against the walls of a fortification, exerted a force which, in some respects, exceeded the utmost effects of our battering cannon, though in others it was probably inferior to the modern ordnance. To compare the effects of the battering-ram, the metal extremity of which suppose equal to a 24 pounder with a cannon-ball of 24 pounds weight; in order that the two bodies may have the same effect in cutting a wall or making a breach in it, the weight of the aries must exceed that of the cannon ball in the proportion of the square of 1700, the velocity of the ball*, to the square of the velocity with which the battering ram could be made to impinge against the wall expressed in feet. If this may be estimated at 10 feet in a second, the proportion of the weights will be that of about 2,890,000 to 100, or of 28,900 to 1; the weight of the battering ram therefore must be 346 tons. In this case the battering-ram and the cannon-ball, moving with the velocities of 10 and 1700 feet respectively in a second, would have the same effect in penetrating the substance of an opposed obstacle: but it is probable that the weight of the aries never amounted to so much as is above described; and consequently the effects of the cannon-ball to cut down walls by making a breach in them, must exceed those of the ancient battering-rams: but the momentum of these, or the impetus whereby they communicated a shock to the whole building, was far greater than the utmost force of cannon-balls; for if the weight of the battering-ram were no more than 170 times greater than that of a cannon-ball, each moving with its respective velocity, the moments of both would be equal; but as it is certain that the weight of these ancient machines was far more than 170 times our heaviest cannon-balls, it follows, that their moment or impetus to shake or overturn walls, &c. was far superior to that which is exerted by the modern artillery. And since the strength of fortifications will in general be proportioned to the means which are used for their demolition, the military walls of the moderns have been constructed with less attention to their solidity and massy weight than the ancients thought a necessary defence against the aries; that sort of cohesive firmness of texture which resists the penetration of bodies being now more necessary than in ancient times: but it is manifest, that even now solidity or weight in fortifications also is of material consequence to the effectual construction of a wall or battery." This difference between the momentum and force of penetration is exemplified in knives, wedges, or

Mechanical
Power.

13

Mr Atwood's observation is, that the place of wood's observation is, that the battering-rams used by the ancients were no less efficient in beating down the walls of cities than the modern artillery.

* See the article Gunnery.

any sharp instruments, where a sudden blow will cause a much deeper penetration than a weight vastly greater than could be stirred from the earth by the force of the blow.

§ 7. Of the Multiplication and Increase of Power.

We have now seen that power, absolutely so called, acts in a kind of double capacity, viz. either when it impresses a great velocity upon a small quantity of matter, or when it impresses a small velocity upon a great quantity of matter. It must, however, be remarked, that the matter we speak of is always supposed subject to the laws of gravity; for what would be the consequence of putting a body in motion which had no gravity we cannot possibly conceive, because we never saw any such body. Philosophers indeed mention the *vis inertia* of matter as property distinct from gravity; but the arguments in favour of this property are now generally looked upon to be inconclusive, and gravity and the *vis inertia* looked upon to be the same.

The two modes in which absolute power acts, come precisely to the same thing whether the velocity be great or small; for it is evident, that when two pounds move with the velocity of 1, it is the same thing with one pound moving with the velocity of 2; the velocities as well as powers being exactly the same. But there is a third way in which power may be directed, in which it has not the relation to velocity already mentioned; and that is, by simple pressure, where no motion is admitted. Thus may the smallest power be made to augment itself to an inconceivable degree, as in fig. 26. Here, suppose the body A to press directly downwards upon the line AB fastened to the small wheel B, moveable upon an axis. If we suppose the extremity of the line at A to be supported so that it shall not fall to a side, the wheel B will press downward with the whole of the weight A upon the line EF, and consequently the line g must sustain the whole of this weight. But if the line EF be supported so that it cannot move perpendicularly downwards to g, it will then roll along the line EF from B towards F; and this tendency to roll in the direction just mentioned will be exactly equivalent to the weight A. Any body therefore laid on the top of a stick set up at an angle of 45 degrees, will require a power double to its own weight to keep it steady at the foot, abstracting from that which will be necessary to prevent it from falling to a side.

If now we suppose the wheel B to press laterally upon another C; and that other, by means of the line CD and wheel D, to press upon the two obstacles i and k, both of which it touches at an angle of 45 degrees; it is plain that not only each of these obstacles must bear the whole weight of the body A, but the reaction of the wheel D will press down the wheel C in the direction Cg with the very same force that D is pressed upwards. This is entirely similar to the case of the man in the boat represented in fig. 1. Thus the weight A produces a pressure equal to five times its own weight; and by multiplying the wheels and rods, we might increase the pressure as much as we please. The case is similar to that in hydrostatics, where a little quantity of liquid may be made to burst the strongest vessel.

SECT. II. Of the Mechanical Powers.

By these we understand such simple machines as are useful for comparing the velocity of various bodies together, and impressing them with greater or smaller degrees of it at pleasure; by which means we may either cause a small weight overcome a great one, or by means of a great one we may make a small weight move through a space proportionably great. Thus by means of some of these powers, indeed by any of them, we may cause a weight of one pound, by moving through the space of ten feet, raise another of ten pounds through one foot; or *vice versa*, by a weight of ten pounds moving through the space of one foot, we may make a single pound move through the space of ten feet; but by none of the powers will we be able, by moving a weight of ten pounds through one foot, to move a single pound through 11 feet; nor by a single pound moving through a space of nine feet will we be able to raise a weight of ten pounds through the space of one foot. None of the mechanic powers, as they are called, therefore, can make any absolute increase of the power applied; all that they can do is to alter the velocity of the power applied, and thus transfer it either to a larger or smaller body at pleasure; and upon this principle depends the whole practical part of mechanics. The mechanical powers are six in number, viz. the lever, wheel in axis or axis in peritrochio, the pulley, inclined plane, wedge, and screw, of all which we shall now treat particularly.

§ 1. Of the Lever.

THIS is the most simple of all the mechanical powers, and is usually no other than a straight bar of wood or iron supported by a prop, as in fig. 27. The weight to be raised is suspended at the short arm of the lever A; and exactly in the inverse proportion of the distance of the weight from the fulcrum or prop C, is the quantity of the weight at B necessary to keep it in equilibrio. Thus if the weight at A be distant one foot or one inch, it signifies nothing which, from the prop, it will require an equal weight placed at the same distance on the other side, as at 1, to balance it; but if the latter be placed at 2, then only half the weight suspended at A will balance it: if the small weight is placed at 3, then only one third will be necessary; if at 4, only one-fourth, &c. and if, as in the figure, it be removed to 10, then only one-tenth part will be required to make a balance. It must still be remembered, however, that if the lever is put in motion, the small weight must move through a space ten times as great as that through which the large one moves; so that in fact there is not any acquisition of power by means of the lever, though it is one of the instruments most commonly used in mechanics, and very serviceable in loosening stones in quarries, or raising great weights to a small distance from the ground; after which they may be raised to greater heights by other machines.

In making experiments with this kind of lever, it is necessary either to have the short arm much thicker than the long one, so that it may exactly balance the latter, or a weight must be appended to it just sufficient to keep it in *equilibrio*, otherwise no accuracy can

Of the steel-yard.

be expected. This lever is the foundation of balances of all kinds, whether of the common kind or of that called the *Roman statera* or steel-yard. The latter is no other than the lever represented in fig. 27. For if a scale is appended to the end A of the lever, and a weight, suppose of one pound, used as a counterpoise to the body which is to be put in the scale, it will show exactly the weight of that body, by putting it at a proper distance from the fulcrum upon the long arm. Thus if the weight when placed at the division 5 counterpoises that placed in the scale, it shows that the body weighs exactly five pounds: if it balances at 6, then it shows that the body weighs six pounds, &c. But for a more particular account of this instrument, see the article *STEEL-YARD*. To this kind of lever may be reduced several kinds of instruments, as scissars, snuffers, pincers, &c.

In levers of this kind, the fulcrum C must support both the weight to be raised and likewise that which raises it; so that the weight upon C must be the greater in proportion as the arm CB of the lever is shorter. Thus, if the arms are both equal, the fulcrum C must bear double the weight at A: if the one arm is double the length of the other, then it has only to bear the weight to be raised, and one half more; because any weight at 2 will balance one double to itself at 1; but if removed to 10, the fulcrum will only have $\frac{1}{10}$ to bear.

16
Second kind of lever.

In some cases, the weight to be raised is placed between the acting power and the fulcrum, as in fig. 28. This lever is more powerful than the other, and is likewise more easily supported, because only part of the weight to be raised, and none of that which raises it, lies upon the fulcrum. Thus in fig. 28. let the extremity A of the lever AB rest upon a fulcrum at o, and let the small weight 1, by means of a string put over the wheel or pin C, pull up the other extremity; this weight 1 will then counterpoise the large one 10, and very little additional force will be required to raise it up. It is also plain, that the whole weight to be raised being 10, the fulcrum sustains only 9 of it, for the other 1 is sustained by the string BC. It is plain also, that a lever of this kind only ten feet long will raise as great a weight as another of the former kind eleven feet in length; nevertheless there is not any absolute gain of power, because the small weight 1 must move through ten times as much space as the large one; and thus the quantity of motion is exactly equal in both. To this kind of lever we may reduce oars, doors turning upon hinges, cutting knives fixed at the point of the blade, &c. From it also we see the reason why two men carrying a burden upon a pole may bear unequal shares of the weight; for the nearer any one of them is to the burden, the greater share he bears; and if he goes directly under it, he must bear the whole. Hence, if two persons of unequal strength are to carry a burden in this manner, the weaker should always be placed at the greatest distance from it.

17
Third kind of lever.

If in this lever the moving power be put in the place of the weight, it acts at a great disadvantage; and a very great power will be requisite to overcome a small weight. The reason of this is plain from an inspection of fig. 28; for it is the same thing whether we suppose the body 10 to be the moving power, or the weight to be raised; in either case, nine-tenths of

it are spent upon the fulcrum at o; and the other tenth part at 10 will be able to do no more than balance the weight 1. Levers of this kind are only made use of when we wish to give a considerable degree of velocity to bodies; and hence the flies of clocks, mill-stones, &c. may be accounted levers of this kind; for in these the moving power is applied to a pinion near the centre of motion, and acts at a great disadvantage; the muscles of the arms or legs of a man, by their insertion near the joints, likewise act as levers of this kind; and hence the power exerted by a muscle is always much greater than the force it has to overcome.

In all cases in which the lever is applied, it is necessary, in order to give it the greatest advantage, that the moving power act in a direction exactly perpendicular to the lever itself. If this be not the case, it lever acts will be necessary to lengthen the lever in proportion to the obliquity. Thus in fig. 29, suppose the straight lever AB to rest on the fulcrum C, so that a weight of one pound may counteract 10; if the lever be bent in the direction AD, it will then be necessary to lengthen it somewhat in order to produce the same effect. If bent in the direction CE, it must be farther lengthened, and still farther if bent in the direction CF. The reason of this is, that when the weight acts on the bended lever ACF, ACE, and ACD, a part of its force is spent in giving, or attempting to give, a lateral motion to the fulcrum C; and the part thus lost is exactly equal to the advantage gained by the greater length of the lever. To make a lever of a determinate length act always with the same power, it will be necessary to have some contrivance by which the moving power may act always perpendicularly to it; as by having two circular pieces of wood or other solid matter fastened to the ends of it, round which the ropes may wrap themselves when it is put in motion, such as are represented by *ab* and *BG* in the figure.

Fig. 30. shows a kind of lever bent so that one part of it may form a right angle with the other. Here the prop or centre of motion is at the angular point C. P is a power acting upon the longer arm AC at F, by means of the cord DE going over the pulley G; and W is a weight of resistance acting upon the end B of the shorter arm BC. If the power be to the weight as BC is to CF, they will remain in equilibrium. Thus suppose W to be five pounds acting at the distance of one foot from the centre of motion C, and P to be one pound acting at F five feet from the centre C, the power and weight will just balance each other. A hammer drawing a nail is a lever of this kind. In this lever the pressure upon the fulcrum downwards is just equal to the weight to be raised; but there is likewise a lateral pressure equal to the weight P; so that the centre of motion must have a double support, otherwise the whole lever with the weight would be drawn towards the side in the direction BC.

If, as in fig. 31. and 32. the lever be bent so as to form two sides of a square, the weight to be raised will always be equal to that upon the fulcrum, in whatever place the fulcrum may be put; but both will vary according to the distance from the angular point. Thus, if as in fig. 31. the fulcrum be placed at the angular point A, the weight F appended to the extremity B

mechanical powers. of the arm AB will juſt counterpoize an equal weight E by means of the ſtring CDE put over the pin D, and drawn laterally by the arm AC. But if, as in fig. 32. the fulcrum be placed nearer to the extremity of the arm AC, as at 3, the cafe will then be very much altered, and one pound ſuſpended at the extremity B of the arm AB will counterpoize four at the extremity C of the other arm: the preſſure on the fulcrum will likewiſe be equal to the weight to be raiſed. Was the fulcrum placed at 2, then a weight of one pound at B would only counterpoize two pounds acting at C; and if it was placed at 1, then a weight of three pounds at B would be requiſite to counterpoize 4 at C.

21 If it is worth notice, that levers of this kind cannot be exactly counterpoized by the power of ſtraight levers. Thus, in fig. 33. let any weight, as C, be appended to B, the extremity of the arm of the bent lever BA4. Let DE be a ſtraight lever, the force of which we deſign to oppoſe to that of the crooked lever. For this purpoſe let another weight F act upon the extremity D of this ſtraight lever by means of a ſtring put over the pin G. Let the two levers be connected together by means of the ſtring h3, and let a piece of wood or iron E4 be put between their two extremities; the two weights being now allowed to act, it is evident that the levers will be pulled in different directions, the ſtring h3 will be tightened, and the extremity E of the ſtraight lever DE will be preſſed towards 4, while the extremity 4 of the crooked lever will be preſſed towards E; by which means the two levers will oppoſe one another in every point of their action. There is not, however, any weight whatever applied to the ſtraight lever which can be made to counterbalance that at C, in ſuch a manner as to keep the bent lever ſteady. Let us firſt ſuppoſe the weights to be each one pound, and the ſtring to be placed as in the figure at h3. In this cafe the weight C pulls the crooked lever from b towards 3, with a force equal to 4, and the extremity 4 will be preſſed towards E with an equal degree of force. But in the ſtraight lever, though the point b be pulled in the direction 3b by a force of four pounds, the extremity E is preſſed the contrary way by a force equivalent only to three. Thus the weight C muſt preponderate, and that at F will aſcend. Let us next add to the weight F one pound; by which means the preſſure from E towards 4 will be augmented to 4, and the two extremities of the levers will counteract each other: but now the preſſure in the direction 3b will be greater by one-third of a pound than it is in the direction h3; and of conſequence the weight F will prevail, the arm AB of the crooked lever and the weight appended to it being raiſed. If we attempt to mend matters by augmenting the weight F by not quite a third part, the extremities of the two levers will not balance each other, the preſſure from 4 to E will be greater than from E to 4; and in like manner the preſſure from 3 to b will be greater than from b to 3. Hence both levers will be pulled in a direction from D towards G, and the weight F will deſcend if the weights be properly adjusted without any aſcent of the other. In ſhort, let us alter the weights as we will, or let us alter the poſition of the fulcrum as we will, it is eaſy to ſee that there is an abſolute impoſſibility that the two levers can counteract each other;

because the preſſure upon the fulcrum of the crooked lever will always be equal to that by its extremity 4; but in the ſtraight lever the preſſure upon the fulcrum muſt neceſſarily be greater than that of the extremity.

These are all the varieties of the lever which can be ſuppoſed; it remains now only to ſhow the reaſon of its action, or why a ſmall weight when at reſt ſhould counterpoize a great one; motion or velocity being here to appearance out of the queſtion, as we cannot attribute any degree of motion to two bodies abſolutely at reſt. To do this in a clear and diſtinct manner has puzzled ſome of the greateſt mathematicians: that of Dr Hamilton profeſſor of philoſophy in Dublin, 22 founded upon the reſolution of forces, ſeems to be the moſt readily underſtood, and leaſt liable to objection. 'The moſt noted theorem in mechanics (ſays he) is this, "When two heavy bodies counterpoize each other by means of any machine, and are then made to move together, the quantities of motion with which one deſcends and the other aſcends perpendicularly will be equal." An equilibrium always accompanying this equality of motions, bears ſuch a reſemblance to the cafe wherein two moving bodies ſtop each other when they meet together with equal quantities of motion, that many writers have thought that the cauſe of an equilibrium in the ſeveral machines might be immediately aſſigned, by ſaying, that ſince one body always loſes as much motion as it communicates to another, two heavy bodies counteracting each other muſt continue at reſt, when they are ſo circumſtanced that one cannot deſcend without cauſing the other to aſcend at the ſame time, and with the ſame quantity of motion. For then, ſhould one of them begin to deſcend, it muſt inſtantly loſe its whole motion by communicating it to the other. This argument, however plauſible it may ſeem, I think is by no means ſatisfactory; for when we ſay that one body communicates its motion to another, we muſt neceſſarily ſuppoſe the motion to exiſt firſt in the one, and then in the other; but in the preſent cafe, where the two bodies are ſo connected that one cannot poſſibly begin to move before the other, the defending body cannot be ſaid to communicate its motion to the other, and thereby make it aſcend: But whatever we ſhould ſuppoſe cauſes one body to deſcend, muſt be alſo the immediate cauſe of the other's aſcending: ſince from the connection of the bodies, it muſt act upon them both together as if they were really but one. And therefore, without contradicting the laws of motion, I might ſuppoſe the ſuperior weight of the heavier body, which is in itſelf more than able to ſuſtain the lighter, would overcome the lighter, and cauſe it to aſcend with the ſame quantity of motion with which the heavier deſcends; eſpecially as both their motions, taken together, may be leſs than what the difference of the weights, which is here ſuppoſed to be the moving force, would be able to produce in a body falling freely.

However, as the theorem above-mentioned is a very elegant one, it ought certainly to be taken notice of in every treatiſe of mechanics, and may ſerve as a very good index of an equilibrium in all machines: but I do not think that we can from thence, or from any one general principle, explain the nature and effects of all the mechanic powers in a ſatisfactory manner:

Mechanical Powers.

22 Dr Hamilton's definition of the properties of the lever.

manner; because some of these machines differ very much from others in their structures, and the true reason of the efficacy of each of them is best derived from its particular structure.

‘The lever is considered as an inflexible line, void of weight, and moveable about a fixed point called its *fulcrum* or prop. The property of the lever, expressed in the most general term, is this: “When two weights, or any two forces, act against each other on the arms of a lever, and are in equilibrium, they will be to each other inversely as the perpendicular or shortest distances of their lines of direction from the fulcrum.”

‘This proposition contains two cases; for the directions of the forces may either meet in a point, or be parallel to each other. Most writers begin their demonstration of this proposition with the second case, which seems to be the simplest, and from which the other may be deduced by the resolution of forces. Archimedes, in his demonstration, sets out with a supposition, the truth of which may reasonably be doubted: for he supposes, that if a number of equal weights be suspended from the arm of a lever, and at points equidistant from each other, whether all these points be at the same side of the fulcrum, or some of them on the opposite side, these weights will have the same force to turn the lever as they would have were they all united and suspended from a point which lies in the middle between all the points of suspension, and may be considered as the common centre of gravity of all the separate weights. Mr Huygens, in his *Miscellaneous observations on mechanics*, says, that some mathematicians have endeavoured, by altering the form of this demonstration, to render its defects less sensible; though without success. He therefore proposed another proof, which is extremely tedious and prolix, and also depends on a postulatam, that, I think, ought not to be granted on this occasion: it is this; “When two equal bodies are placed on the arms of a lever, that which is furthest from the fulcrum will prevail and raise the other up.” Now, this is taking it for granted, in other words, that a small weight placed further from the fulcrum, will sustain or raise a greater one. The cause and reason of which fact must be derived from the demonstration that follows, and therefore this demonstration ought not to be founded on the supposed self-evidence of what is partly the thing to be proved.

‘Sir Isaac Newton’s demonstration of this proposition is indeed very concise; but it depends on this supposition, that when from the fulcrum of a lever several arms or radii issue out in different directions, all lying in the same vertical plane, a given weight will have the same power to turn the lever from which-ever arm it hangs, provided the distance of its line of direction from the fulcrum remains the same. Now it must appear difficult to admit this supposition, when we consider that the weight can exert its whole force to turn the lever only on that arm which is the shortest, and is parallel to the horizon, and on which it acts perpendicularly; and that the force which it exerts, or with which it acts perpendicularly, on any one of the oblique arms, must be inversely as the length of that arm, which is evident from the resolution of forces.

‘Mr Maclaurin, in his *View of Newton’s Philosophy*, after giving us the methods by which Archimedes and Newton prove the property of the lever, proposes one of his own, which, he says, appears to be the most natural one for this purpose. From equal bodies, sustaining each other at equal distances from the fulcrum, he shows us how to infer that a body of one pound (for instance) will sustain another of two pounds at half its distance from the fulcrum; and from thence that it will sustain one of three pounds at a third part of its distance from the fulcrum: and going on thus, he deduces, by a kind of induction, what the proportion is in general between two bodies that sustain each other on the arms of a lever. But this argument, were it otherwise satisfactory, yet as it cannot be applied when the arms of the lever are incommensurable, it cannot conclude generally, and therefore is imperfect.

‘There are some writers on mechanics, who, from the composition of forces, demonstrate that case of the general proposition relating to the lever, in which the directions of the forces are oblique to each other, and meet in a point: but I do not find that they have had any other way of proving the second case, in which the directions of the forces are parallel, but by considering these directions as making an angle with each other, though an infinitely small one, or as meeting at an infinite distance; which way of reasoning is not to be admitted in subjects of this kind, where the proof should always show us, directly from the laws of motion, why the conclusion must be true, in such manner that we might see clearly the force of every step from the first principles down to the conclusion, which we are prevented from doing when any such arbitrary and inconsistent supposition is introduced.

‘From thus considering the various proofs that have been given of this fundamental proposition in mechanics, we may see the reason why many subsequent writers have appeared dissatisfied with the former demonstrations, and have looked for new ones: I shall now propose two methods of demonstrating it, merely from the composition and resolution of forces. The proposition may be expressed as follows.

“When three forces act upon an inflexible line, whether straight or crooked, and keep it in equilibrium, any two of them will be to each other inversely as the perpendicular distances of their lines of direction from that point to which the third force is applied.”

‘Let the three forces E, G, F, (fig. 34.) act upon three points A, B, D, in an inflexible line; and first let the directions of the forces E and F (which act on the same side of the line) meet in the point C. Then it is evident that the force, which is compounded of these two, must act upon the line A B D in the direction of a right line that passeth through the point C; consequently the force G, which sustains this compounded force, must be equal thereunto, and must act in a contrary direction; therefore the force G must act in the direction of the line C B. From the point B draw B H and B K perpendicular to the directions of the forces E and F, and draw B M and B N parallel to these directions, forming the parallelogram B M C N; then, since these three forces are

Mechanical powers.

Mechanical powers.

in equilibrium, they must be to each other respectively as the sides and diagonal of this parallelogram to which their directions are parallel; therefore E is to F as CM to CN or MB, that is, (because the sides of a triangle are as the lines of the opposite angles) as the line of the angle MBC, or its alternate one BCN, to the line of the angle BCM; but making CB the radius, BK is the line of the former angle, and BH of the latter; therefore E is to F as BK to BH; so that the forces E and F are to each other inversely as the perpendicular distances of their lines of direction from the point B, on which the third force G acts. Now to compare the forces F and G together: From the point A, on which the third force acts, draw AB and AL perpendicular to the directions of the forces G and F; then, as was said before, F is to G as MB is to CB; but MB is to CB as AB to AL; because, making CA the radius, AB is the line of the angle MCB, and AL is the line of the angle MCN, or CMB its supplement, to two right ones; therefore the forces F and G are to each other inversely as the perpendicular distances of their lines of direction from the point A, on which the third force E acts; and thus the first case of the proposition is proved, in which the forces act against each other in oblique directions.

We must now consider what parts of the forces E and F act against the force G in directions parallel to GC; for it is such parts only that really oppose the force G, and keep it in equilibrium; and from thence we shall see what proportion two forces must have to each other when they are in equilibrium, and act in parallel directions. Let the three forces act upon the points A, B, and D, (fig. 35.); let them be in equilibrium, and their lines of direction meet in the point C, as in the preceding case; then, if the points A, B, and D, are not in a right line, draw the line AD meeting BC in P, and from P draw PN and PM parallel to the directions of the forces E and F; through the points A and D draw parallel lines to BC; and through B draw a perpendicular to these lines, meeting them in H and K; from the point M draw MO parallel to AD, and meeting BC in O. Now the three forces E, G, and F, that are in equilibrium, will be to each other respectively as the sides of the triangle CMP, as in the preceding case; but the force P, which is denoted by the line MC, may be resolved into two forces acting in the directions MO and OC, the former of these only urges the point A towards D, and the latter acts in direct opposition to the force G; in like manner the force F, which is denoted by the line PM, may be resolved into two forces acting in the directions OM and PO, the former of which only urges the point D towards A, and the latter acts in direct opposition to the force G; now it is evident that the force G, which is denoted by the line PC, is sustained only by those parts of the forces E and F which act against it, in directions parallel to BC, and are denoted by the lines OC and PO, which, taken together, are equal to PC; for the other parts of the forces E and F, which are denoted by MO, are lost, being equal, and contrary to each other: if, therefore, instead of the forces F and E, we suppose two other forces, R and L, to act on the points D and A, in directions parallel to BC, and to keep the force G in equilibrium, it follows, from what has

been proved, that R and L taken together will be equal to G, and that these three forces will be to each other respectively as the lines PO, OC, and PC; therefore R will be to L as PO to OC, (that is, as AM to MC, or as AP to PD, or) HB to BK; consequently the forces R and L are to each other inversely as the perpendicular distances of their lines of direction from the point B, to which the third force is applied. Now to compare the forces R and G together; since the forces R and L may be denoted by BH and BK, and are both together equal to G, that force will be denoted by the whole line KH, and therefore R will be to G as BH to KH; so that these forces are also to each other inversely as the perpendicular distances of their lines of direction from the line of direction of the third force L; and thus the second case of the proposition is proved, in which the forces act against each other in parallel directions. If the point in the inflexible line, to which one of the forces is applied, should become a fixed point, or *fulcrum*, round which the line may turn, it is evident that the other two forces will continue in equilibrium, as they were before; and therefore the property of the lever, in all cases, is manifestly proved by this proposition.

The centre of gravity of a body is said to be that point which being sustained, or prevented from descending, the body will continue at rest. From hence it follows, that when a body hangs freely from a single point and continues at rest, its centre of gravity will lie perpendicularly under the point of suspension; for in that situation only it will be sustained, and can defend no lower.

From this property, which agrees likewise to the common centre of gravity of two bodies joined together by an inflexible right line, and which may then be considered as one, I shall show that their centre of gravity is a point in the line that joins them together, so situated that the distances of the two bodies from it are to each other inversely as their weights. This theorem concerning the position of the common centre of gravity of two bodies, which is a very noted one in mechanics, I have never seen demonstrated otherwise than by inferring it from the general property of the lever: but I think the method I shall now propose of deducing it directly from the definition of the centre of gravity, is the most concise as well as the most natural, and besides it will afford us a very easy way of demonstrating the property of the lever.

Let the two bodies A and B (fig. 36.) be joined by an inflexible right line passing through their centres of gravity, and let them be suspended from the fixed point or pin at P, by the threads AP and BP, so that they may hang freely in such a position as their joint gravity will give them. When these bodies continue at rest, their common centre of gravity must lie directly under the point of suspension, or in the perpendicular line PL, consequently it must be at the point C, the intersection of the lines PL and AB; the position of which point, in the line AB, will be determined by finding out the proportion between the segments CA and CB. If the inflexible line was not interposed between these bodies, they would move till their threads coincided with the perpendicular line PL; since therefore they are kept at stand by this line, they must urge it with certain forces in opposite directions; and these

Mechanical
powers.

urging forces must be equal, since the line on which they act continues at rest: and therefore the force with which each body urges the other in the direction of this line, may be denoted by the same letter U, and we may denote the weights of the two bodies respectively by the letters A and B. Now the body A is acted upon by three forces, viz. by its weight A in the direction PC, by the force U with which the other body urges it in the direction CA, and by the reaction of the pin in the direction AP; and since these three forces are in equilibrio, and keep the body at rest, they are to each other respectively as the sides of the triangle FCA; therefore A is to U, as PC to CA. In like manner, the body B is urged by three forces, viz. its weight B in the direction PC, the urging force U in the direction CB, and the reaction of the pin in the direction BP, which forces are to each other as the sides of the triangle PCB; therefore U is to B, as CB to PC; and therefore (*ex aequo perturbate*) A is to B, as CB to CA; consequently the weights of the bodies A and B are to each other directly as their distances from the point C, which lies directly under the point of suspension, and is therefore their common centre of gravity.

When two bodies are connected by an inflexible line, and this line is supported by a prop so that their centre of gravity cannot descend, the bodies must continue to rest, and will be in equilibrio. Therefore it is easy to see how, from the theorem now demonstrated, we may prove the property of the lever in that case where the directions of the forces are parallel; and from thence the other case, in which the directions are oblique to each other, may be deduced by the resolution of forces, as is usually done. And this is the second method by which I said the general property of the lever might be strictly demonstrated.

The lever is the most simple of all the mechanic powers; and to it may be reduced the balance and the axis in *peritrochio*, or axle and wheel: Though I do not consider the balance as a distinct mechanic power, because it is evidently no other than a lever fitted for the particular purpose of comparing the weights of bodies, and does not serve for raising great weights or overcoming resistances as the other machines do.

23
Another
demonstration.

Though this demonstration will no doubt be abundantly clear to mathematical readers, yet to others less versed in that science its appearance will no doubt be somewhat obscure and perplexed. The following we subjoin as less intricate.

Let AB, fig. 37, represent a straight rod of wood or iron, fastened at the extremity A, at right angles to another piece of the same, and kept steady by two pins C and D. If a weight be put upon the extremity H of the upright rod AH, it will press down that, and along with it the horizontal rod AB, so that every point in the rod will move with the whole force of the weight. Thus, whether we suppose an obstacle to be placed at the extremity B, at the point 2, or at 1, in the horizontal rod AB, it will have exactly the force of the weight placed at H to overcome.—Supposing then that the weight would make the whole descend from A to E in one second; then it is plain that the whole power exerted by the rod in its descent would be exprest by the parallelogram ABEF. But if, instead of supposing the line AB to be the full

length represented in the figure, we suppose it to be only half that length, and cut off at 1, then the power of the weight would be represented by the parallelogram A 1 E 1. Were it still farther shortened, by being cut off at 2, then the power would be represented by the parallelogram A 2 E 2; and each of these parallelograms, however unequal they may be as represented upon paper, would in reality be equal when the experiment was made, because in no case could the weight descend with a greater force than its own. Suppose next the weight to be taken off from H, and put upon B, and the rod AB to be moveable upon the centre A; the whole power of the weight then would be exprest by the triangle ABG, equal to the parallelogram ABEF; but as every point of the lever must bear the whole impulse of the weight as before, it is plain, that as we approach towards the centre, that power is compressed into less and less space. Thus, when the weight has descended from B to G, though the large triangle ABG be equal to the parallelogram ABEF, yet the smaller triangle A 1 1 is equal only to one half of the parallelogram A 1 E 1, which represents the power. The whole power being therefore compressed into half the space, must of necessity be double to what it was in the former case. In like manner, the triangle A 2 2, is only equal to one half of the parallelogram A 2 E 2; and this parallelogram itself is only half the space representing the whole power of the weight. In this case, therefore, the power is confined within one fourth part of the space which it naturally has, and for that reason must be four times as great.

§ 2. Of the Wheel and Axle, or Axis in Peritrochio.

THIS power acts entirely upon the principles of the lever, and has therefore sometimes been called a perpetual lever. In it the power is applied to the circumference of a wheel by means of a rope or otherwise, the weight to be raised being fastened to a rope which winds round the axis. It is represented fig. 38, where AB is the wheel, EDF its axis, P the moving power, and W the weight to be raised by means of the rope K coiling itself about the axis. It is plain then from an inspection of the figure, that when the large wheel has made one revolution, the weight P will have descended through a space equal to the circumference, and as much of the cord I, by which it is suspended, will be wound off. On the other hand, the weight W will have ascended only through a space equal to the circumference of the axle, and just so much of the rope K will be wound up upon it. As the circumference of the wheel, therefore, is to that of the axis, so will the velocity of the moving power be to that of the weight to be raised, and of consequence such will be the force of the machine: thus, if the circumference of the wheel be eight, ten, twelve, or any number of times as large as that of the axle, one pound applied to the circumference will counter-balance eight, ten, twelve, or more pounds, applied to the axle, and a small addition will raise it up.

The engines called cranes, for raising great weights, are no other than wheels of this kind. Sometimes they are moved by handles S, S, &c. placed on the circumference of the wheel, which is turned by mens hands, as is shown fig. 38. Sometimes the wheel is hollow, and

Mechanical
powers.

24
Of the engines called cranes.

furnished

Mechanical powers. furnished with steps, on which a man, who is inclofed in the wheel, continually fets his feet, as if he was afcending a flair; and thus the wheel yielding to his weight turns round, and coils up the rope which raifes the weight about its axis. When the crane is to be turned by mens hands, it may advantageouſly have cogs all round the circumference, in which a ſmall trundle may be made to work and be turned by a winch.— Thus the power of the man who works it will be greatly increaſed; for his ſtrength will be augmented as many times as the number of revolutions of the winch exceeds that of the axle D, when multiplied by the exceſs of the length of the winch above the length of the ſemidiameter of the axle, added to the ſemidiameter or half the thickneſs of the rope K, by which the weight is drawn up. Thus, ſuppoſe the diameter of the rope and axle taken together to be 12 inches, and conſequently half their diameters to be 6 inches, ſo that the weight W will hang at fix inches perpendicular diſtance from below the centre of the axle; let us ſuppoſe the wheel AB, which is fixed on the axle, to have 80 cogs, and to be turned by means of a winch fix inches long, fixed on the axis of a trundle of eight flaves or rounds, working in the cogs of the wheel. Here it is plain that the winch and trundle would make ten revolutions for one of the wheel AB, and its axis D, on which the rope K winds in raiſing the weight W: and the winch being no longer than the ſum of the ſemidiameters of the great axle and rope, the trundle could have no more power on the wheel than a man could have by pulling it round by the edge, becauſe the winch would then have no greater velocity than the edge of the wheel has, which is ſuppoſed to be ten times the velocity of the riſing weight; ſo that in this caſe the acquisition of power would be as 10 to 1. But if the length of the winch be 12 inches, the power gained will be as 20 to 1; if 18 inches, which is a ſufficient length for any man to work with, the acquisition of power will be as 30 to 1; becauſe the velocity of the handle would be 30 times as great as that of the riſing weight, and the abſolute force of any machine is exactly in proportion to the velocity of the weight raiſed by it. We muſt always remember, whoever, that juſt as much time is loſt in working the machine as there is power gained by it; for none of the mechanical powers are capable of gaining both power and velocity at the ſame time.

In all cranes, it is neceſſary to have a racked wheel, repreſented by G, on one end of the axle, with a catch H to fall into its teeth; which will at any time ſupport the weight, and keep it from deſcending, if the workman ſhould happen to let ſlip his hold. For want of this precaution, terrible accidents have ſometimes happened to people incloſed in cranes, by their inadvertently miſſing a ſtep.

§ 3. Of the Pulley.

The pulley is a ſingle wheel of wood, braſs, or iron, moveable upon an axis, and incloſed in a kind of caſe called its *block*, which admits of a rope to paſs freely over the circumference of the pulley, in which alſo there is uſually a groove to keep the rope from ſliding, the axis being generally fixed in the block.

In ſome pulleys the block is fixed; in others moveable, and riſes with the weight. Both theſe kinds are repreſented, fig. 39. AA ſhows a fixed pulley, with its block b. Over the wheel a ſtring BB paſſes, to the extremities of which are fixed the two weights W and P. This pulley, however, though it changes the direction of a power, yet does not gain any advantage; for one of the weights muſt always deſcend as much as the other aſcends, of conſequence their velocities muſt always be equal; and when this is the caſe, there can be neither increaſe nor decreaſe of power. A ſingle fixed pulley, therefore, though it may compare the weight of two bodies together, cannot be accounted in any reſpect a mechanical power. But if with a fixed pulley we combine a moveable one, or one in which the block ariſes along with the wheel, we gain an increaſe of one half. Thus if a weight W hangs at the lower end of the moveable block P of the pulley D, and the cord GF goes under the wheel, it is plain that the half G of the cord bears one half of the weight W, and the half F the other. The hook H, therefore, which ſuſtains the half G of the cord, muſt therefore bear one half of the weight; and if the cord at F be drawn up, ſo that the pulley may be raiſed from D to C, the ſtring will be extended to its whole length, all but that which goes under the wheel of the pulley D; but the weight or power P by which the ſtring is thus drawn up, will have moved twice as far as the weight W which is drawn up: whence we ſee that only one pound at P will be requiſite to counterpoize two pounds at W. If the upper and fixed block contain two pulleys, and the lower one U contain alſo two, the advantage gained by this combination will be as 4 to 1. Thus, if one end of the ſtring KMOQ be fixed to a hook at I, and the ſtring paſſes over the pulleys N and R, and under thoſe L and P, the weight T of one pound will balance a weight W of four pounds, ſuſpended by a hook from the moveable block, making allowance for the weight of the block itſelf. In like manner will the pulleys give an advantage of 4 to 1 when diſpoſed as at X and Y; but in all caſes the force relation between velocity and power is preferred as in the lever and axis in peritrochio, viz. if the power balances twice its own weight, it muſt move or have a tendency to move through twice the ſpace; if it balances four times its weight, then it muſt have a tendency to move through four times the ſpace that the other does.

Pulleys are of great uſe in practical mechanics, as Advant-
by their means great weights may be raiſed to any ges and dif-
height much more expeditiouſly than by any other advantages
method, and the ſmallneſs of their weight makes of pulleys.
them very convenient for carriage. At ſea they are uſed for hoifting the ſails and yards, ſtraightning ropes, &c. Archimedes, by means of a machine compoſed of pulleys, is ſaid to have drawn a ſhip along this ſtrand, in the preſence of Hiero king of Syracuſe; but this is ſcarcely to be credited, on account of the great friction which attends this kind of machines.— The friction ariſes from three cauſes: 1. The diameter of the axis bearing a conſiderable proportion to that of the wheels. 2. Their rubbing againſt their blocks, or againſt one another. 3. The ſtiffneſs of the rope that goes over and under them. All theſe

causes must necessarily be augmented, in proportion to the weight we have to overcome : and when we consider the immense resistance which a ship must make, with the strength and stiffness of the ropes necessary to overcome it, we can scarce suppose the strength of any individual equal to the task. Pulleys have often been used by inhuman tyrants, in constructing machines for torturing the objects of their cruelty.

26
Reason of
the effects
of the pul-
ley.

The pulley has by some writers been reduced to the lever as well as the wheel and axis ; in which method they consider the fixed pulleys as a lever of the first, and the moveable pulley as one of the second kind : but it is justly observed by Professor Hamilton, that the pulley cannot be with any propriety reduced to a lever ; because, though both the moveable and immoveable pulleys should be taken away, the ropes would have to sustain the same weight that they do with the pulleys ; nay, the very same advantages would be gained by the mere use of pins, without any wheels, were not the friction very great even upon the smoothest pins that could be made use of. It is, indeed, merely to avoid this resistance on the pins that wheels are made use of at all. The best method of computing the power, and explaining the reason of the effects of pulleys, is by considering that every moveable pulley hangs by two ropes equally stretched, each of which bears one half of the weight ; and therefore, when the same rope goes round a number of fixed and moveable pulleys, since all its parts on each side of the pulleys are equally stretched, the whole weight must be equally divided amongst all the ropes by which the moveable pulleys hang ; consequently, if the power which acts on one rope be equal to the weight divided by the number of ropes, that power will sustain the weight.

27
Mr White's
patent pul-
ley.

Plate
CCLXXXVII.

A very considerable improvement in the construction of pulleys has been made by Mr James White, who has obtained a patent for his invention, and of which the following description is given by the inventor. Fig. 68 shows the machine, consisting of two pulleys Q and R, one fixed and the other moveable. Each of these has six concentric grooves, capable of having a line put round them, and thus acting like as many different pulleys, having diameters equal to those of the grooves. Supposing then each of the grooves to be a distinct pulley, and that all their diameters were equal, it is evident that if the weight 144 were to be raised by pulling at S till the pulleys touched each other, the first pulley must receive that length of line as many times as there are parts of the line hanging between it and the lower pulley. In the present case, there are 12 lines, b, d, f, &c. hanging between the two pulleys, formed by its revolution about the six upper and six lower grooves. Hence as much line must pass over the uppermost pulley as is equal to twelve times the distance of the two. But, from an inspection of the figure, it is plain, that the second pulley cannot receive the full quantity of line by as much as is equal to the distance betwixt it and the first. In like manner, the third pulley receives less than the first by as much as is the distance between the first and third ; and so on to the last, which receives only one twelfth of the whole. For this receives its share of line n from a fixed point in the up-

per frame, which gives it nothing ; while all the other Mechanical powers in the same frame receive the line partly by turning to meet it, and partly by the line coming to meet them.

Supposing now these pulleys to be equal in size, and to move freely as the line determines them, it appears evident, from the nature of the system, that the number of their revolutions, and consequently their velocities, must be in proportion to the number of suspending parts that are between the fixed point above-mentioned and each pulley respectively. Thus the outermost pulley would go twelve times round in the time that the pulley under which the part n of the line, if equal to it, would revolve only once ; and the intermediate times and velocities would be a series of arithmetical proportionals, of which, if the first number were 1, the last would always be equal to the whole number of terms. Since then the revolutions of equal and distinct pulleys are measured by their velocities, and that it is possible to find any proportion of velocity on a single body running on a centre, viz. by finding proportionate distances from that centre, it follows, that if the diameters of certain grooves in the same substance be exactly adapted to the above series (the line itself being supposed inelastic, and of no magnitude), the necessity of using several pulleys in each frame will be obviated, and with that some of the inconveniences to which the use of the pulley is liable.

In the figure referred to, the coils of rope by which the weight is supported are represented by the lines a, b, c , &c. ; a is the line of fraction, commonly called the fall, which passes over and under the proper grooves, until it is fastened to the upper frame just above n . In practice, however, the grooves are not arithmetical proportionals, nor can they be so ; for the diameter of the rope employed must in all cases be deducted from each term ; without which the smaller grooves, to which the said diameter bears a larger proportion than to the larger ones, will tend to rise and fall faster than they, and thus introduce worse defects than those which they were intended to obviate.

The principal advantage of this kind of pulley is, that it destroys lateral friction, and that kind of shaking motion which are so inconvenient in the common pulley. " And lest (says Mr White) this circumstance should give the idea of weakness, I would observe, that to have pins for the pulleys to run on, is not the only nor perhaps the best method ; but that I sometimes use centres fixed to the pulleys, and revolving on a very short bearing in the side of the frame, by which strength is increased, and friction very much diminished ; for to the last moment the motion of the pulley is perfectly circular : and this very circumstance is the cause of its not wearing out in the centre as soon as it would, assisted by the ever increasing irregularities of a gullied bearing. These pulleys, when well executed, apply to jacks and other machines of that nature with peculiar advantage, both as to the time of going and their own durability ; and it is possible to produce a system of pulleys of this kind of six or eight parts only, and adapted to the pockets, which, by means of a skin of sewing silk, or a clue of common thread, will raise upwards of an hundred weight.

mechanical
powers.

§ 4. Of the Inclined Plane.

Plate
LXXXIV.

THIS power is represented fig. 40; and the advantage gained by it is exactly in the proportion of the length of the plane to the perpendicular height of it. Thus, let AB be a plane parallel to the horizon, and CD one inclined to it: suppose also the whole length CD to be three times as great as the perpendicular height GF; in this case, the cylinder E will be supported upon the plane CD, and kept from rolling down upon it, by one-third part of its weight. Were the length of the plane four times its height, it would be prevented from rolling down by one-fourth part of its weight. The force with which a rolling body descends upon an inclined plane will be to that with which it would descend by the power of gravity, as the height of the plane is to the length of it.—For, suppose the plane AB (fig. 41.) to be parallel to the horizon, the cylinder C will keep at rest upon any part of the plane on which it is laid. If the plane be so elevated as in fig. 42. that its perpendicular height D be equal to one half of its length AB, then the cylinder will roll down with half its weight; for it would require a power (acting in the direction AB) equal to half its weight to keep it from rolling. If the plane be elevated so as to be perpendicular to the horizon, as in fig. 43. the cylinder C will descend with its whole force of gravity, because the plane contributes nothing to the support or hinderance of it; for which reason, it must require a power equal to the whole force of its gravity to keep it from descending.

If, as in fig. 44. the cylinder C be made to turn upon slender pivots in the frame D, which is furnished with a hook, with a line G fastened to it; if this line go over the fixed pulley H, and have its other end tied to the hook in the weight I; if the weight of the body I be to the weight of the cylinder C, added to that of its frame D, as the perpendicular height of the plane LM is to its length AB; the weight will just support the cylinder, and a small force will make it either ascend or descend. In the time that the cylinder moves from A to B, it must rise through the whole height of the plane ML, and the weight will descend from H to K, through a space equal to the whole length of the plane AB. If the plane be now made to move upon rollers or wheels as in fig. 45. and the cylinder be supported upon it, the same power will draw the cylinder up the plane, provided the pivots of the wheels be small, and the wheels themselves pretty large. For let the machine ABC, equal in height and length to ABM, fig. 44. be furnished with four wheels, of which two are seen at D and E, the third being under C, while the fourth is concealed by the board *a*. Let the cylinder F be laid upon the lower end of the inclined plane CB, and the line G be extended from the frame of the cylinder about six feet, parallel to the plane CB, and fixed in that direction to a hook in the wall, which will keep the cylinder from rolling off the plane. Let one end of the line H be tied to a hook at C in the machine, and the other to a weight K, the same which drew the cylinder up the plane before. If this line be put over the fixed pulley I, the weight K will draw the machine along the horizontal plane L, and under the cylinder F; and when the machine has been drawn the whole

length CB, the cylinder will be raised to *d*, equal to Mechanical the perpendicular height AB above the horizontal powers.

The inclined plane, considered as a mechanical power, may easily be reduced to the lever; for the power acquired by it is always in the proportion of the length to the height, in the same manner as the power acquired by a lever is in the proportion of the long arm to the short one. To compute, or show the reason of the power of an inclined plane, therefore, we have only to construct a lever, the long arm of which is equal to the length of the plane, and the short arm to the height of it; then, whatever weight put upon the long arm counterpoises another put upon the short one, will also keep the same weight from rolling down the inclined plane.

To the inclined plane belong also the wedge, and all cutting instruments which act as wedges, as knives, hatchets, &c. From the theory of the inclined plane also combined with that of falling bodies, we deduce some of the most remarkable properties of the pendulum. See PENDULUM.

§ 5. Of the Wedge.

THIS may be considered as two equally inclined planes DEF and CEF, fig. 46. joined together at their bases e FO: DC is the whole thickness of the wedge at its back ABCD, where the power is applied; EF is the depth or height of the wedge; DF the length of one of its sides, equal to CF the length of the other side; and OF is its sharp edge, which is entered into the wood or other matter to be split, by the force of a hammer or mallet striking perpendicularly upon its back. Thus, AB fig. 47. is a wedge driven into the cleft CED of the wood FG.

When the wood does not cleave at any distance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the resistance of the wood acting against the two sides of the wedge: if the power be to the resistance as half the thickness of the wedge at its back is to either of its sides, and if the power be increased so as to overcome the friction of the wedge, and the resistance arising from the cohesion of the wood, the wedge will be driven in, and the wood split. But when the wood splits, as it commonly does, before the wedge, the power impelling the latter will not be to the resistance of the wood as half the thickness of the wedge is to one of its sides, but as half its thickness is to the length of the other side of the cleft, estimated from the top or acting part of the wedge; for if we suppose the wedge to be lengthened down to the bottom of the cleft at E, the same proportion will hold; namely, that the power will be to the resistance, as half the thickness of the wedge is to the length of either of its sides; or which is the same thing, as the whole thickness of the wedge is to the length of both its sides.

To prove this, let us suppose the wedge is divided lengthwise into two equal parts; in which case, it will become two equally inclined planes, one of which, as *abc* fig. 48. may be made use of for separating the moulding *cd* from the waincot AB. It is evident, that when this half wedge has been driven its whole length *ac* between the waincot and mouldings, its inside *a*: will be

Reason of
the effects
of the inclined
plane.

Plate
CCLXXXV

Mechanical
powers.

be at cd , and the moulding will be separated to fg from the waifcoat. But, from what has been already shown concerning the inclined plane, it appears, that, to have an equilibrium between the power impelling the half wedge and the resistance of the moulding, the former must be to the latter as ab to ac , that is, as the thickness of the back which receives the stroke is to the length of the side against which the moulding acts. Since, therefore, the power upon the half wedge is to the resistance against its side as the half back ab is to the whole side ac , it is plain that the power upon the whole wedge, where the whole thickness is double the half-back, must be to the resistance of both its sides as the thickness of the whole back is to the length of both sides of the cleft, when the wood splits at any distance before the wedge: For when the wedge is driven quite into the wood, and the latter splits at ever so small a distance before it, the top of the wedge then becomes the acting part, because the wood does not touch it any where else. And since the bottom of the cleft must be considered as the place where the whole resistance is accumulated, it is plain from the nature of the lever, that the farther the power is from the resistance, the greater advantage it acts with.

29
Reason of
the effects
of the
wedge.

Some have supposed, that the power of the wedge was in the proportion of the thickness of it to the length of one of its sides; but from what has already been advanced, it is plain that this cannot be the case. The wedge, as has already been shown, is composed of two inclined planes, each of which has a perpendicular height of only one half the thickness of the wedge. As the power of the inclined plane therefore is always as the length to its perpendicular height, it is evident that the power of each of these inclined planes of which the wedge is composed must be as the length of one side to half the thickness; and consequently the power of both must be as the length of both sides is to the whole thickness.

The power of the wedge is exceedingly great, inasmuch that not only wood but rocks may be split by it, which could scarce be done by any of the other powers: but in this it is assisted by percussion of the hammer which drives it, and shatters the stone in a manner that could scarcely be done by any simple pressure.—Wedges as well as pulleys have also been used as instruments of torture.

§ 6. Of the Screw.

THIS is the strongest of all the mechanical powers, though it cannot be accounted a simple one, as no screw can be made use of without a lever or winch to assist in turning it. We may suppose it made by cutting a piece of paper into the form of an inclined plane or half wedge, and then wrapping it round a cylinder, as in fig. 49. From this figure it is evident, that the winch which turns the cylinder must move once round in the time that the paper describes one spiral; and consequently if any weight or greater power of resistance were applied, the winch must turn once round in the time that the weight would move from one spiral thread to another, from d to c for instance. Hence the force of the screw will be as the circumference of the circle defined, by the lever or winch by which it is turned, is to the distance between

the threads of the screw itself. Thus, supposing the distance of the threads to be half an inch, and the length of the winch twelve inches, the circle described by the extremity of it where the power acts will be nearly 76 inches, or about 152 times the distance between the threads; whence a single pound acting at the end of such a winch would balance 152 at the extremity of the screw; and as much more as can overcome the friction would turn the winch and raise up the weight.

Fig. 50. represents a machine for exhibiting the force of the screw. Let the wheel C have upon its axis a screw ab , working in the teeth of the wheel D, which suppose to be 48 in number. It is plain that every time the screw ab and wheel C are turned round by the winch A, the wheel D will be moved one tooth by the screw; and therefore in 48 revolutions of the winch, the wheel D will be turned once round. If then the circumference of a circle described by the handle of the winch A be equal to the circumference of a groove e round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Consequently if the line G goes round the groove e , and has a weight of 48 pounds hung to it below the pedestal EF, a power of one pound at the handle will balance that weight. If the line G goes round the axle I instead of the groove of the wheel D, the force of the machine will be as much increased as the circumference of the groove e is greater than that of the axle; which, supposing to be six times, then one pound at H will balance 288 pounds suspended by the line at the axle.

The screw is of very extensive use in mechanics, its great power rendering it more eligible for compressing bodies together than any of the rest, and the great disparity betwixt the velocity of the handle and that of the threads of the screw, rendering it proper for dividing space into an almost infinite number of parts. Hence, in the construction of many mathematical instruments, such as telescopes, where it is necessary to adjust the focus to the eyes of different people, the screw is always made use of in order to move the eyeglasses a very little nearer or farther away from the object glass. In the 71st volume of the Philosophical Transactions, a new method of applying the screw, so as to make it act with the greatest accuracy, is described by Mr Hunter surgeon. The following are the general principles upon which this method depends.

1. That the strength of the several parts of the engine be adjusted in such a manner to the force they are intended to exert, that they shall not break under the weight they ought to counteract, nor yet encumber the motion by a greater quantity of matter than is necessary to give them a proper degree of strength.
2. That the increase of power by means of the machine be so regulated, that while the force we can exert is thereby rendered adequate to the effect, it may not be retarded in procuring it more than is absolutely necessary.
3. That the machine be as simple as is consistent with other conditions.
4. It ought to be as portable, and as little troublesome as possible in the application.
5. The moving power must be applied in such a manner as to act to the greatest advantage; and that the

the force of the
screw.

31
Mr Hunter's improvement
on the screw.

mechanical powers. the motion ultimately produced may have that direction and velocity which is most adapted to the execution of the ultimate design of the machine.

6. Of two machines, equal in other respects, that deserves the preference in which the friction least diminishes the effect proposed by the whole.

To attain all these advantages in any machine is perhaps impossible; but in the application of the screw, the following method promises to be attended with several of them.

Let AB (fig. 51.) be a plate of metal, in which the screw CD plays, having a certain number of threads in an inch, suppose 10. Within the screw CD there is a female screw*, which receives the smaller screw DE of 11 threads in an inch. This screw is kept from moving about with the former by means of the apparatus at AFG B. But if the handle CKL be turned ten times round the screw, CD will advance an inch upwards; and if we suppose the screw DE to move round along with CD, the point E will advance an inch. If we now turn the screw DE ten times backward, the point E will move downwards $\frac{10}{11}$ ths of an inch, and the result of both motions will be to lift the point E $\frac{1}{11}$ th of an inch upwards. But if, while the screw CD is turned ten times round, DE be kept from moving, the effect will be the same as if it had moved ten times round with CD, and been ten times turned back; that is, it will advance $\frac{10}{11}$ of an inch. At one turn, therefore, it will advance upwards $\frac{1}{11}$ of an inch, and the result of both motions will be to lift the point E $\frac{1}{11}$ th of an inch upwards. If now the handle be six inches long, the power to produce an equilibrium must be to the weight as 1 to $110 \times 6.2832 \times 6 = 4146.912$. Thus the force of Mr Hunter's screw is greatly superior to that of the common one; for in order to have as great a power on the plan of the latter, it must have 110 threads in an inch, which would render it too weak to resist any considerable violence.

With regard to the second general maxim above laid down, Mr Hunter considers both kinds of screws as equally applicable, only that the more complicated structure, and consequently greater expence of his screw, renders it convenient to use the common screw where only a small increase of power is necessary, and his improved one where a great power is wanted. By shortening the handle also, the whole machine is rendered more portable and less troublesome in the using.

To answer the fifth intention, both seem to be equally proper; but for the sixth, the preference must be given to such as best answer the particular purpose proposed. Thus if the screw DE be designed to carry an index which must turn round at the same time that it rises upward, the common screw is preferable; though our author also proposes a method by which his screw may answer the same purpose: With this view a still smaller screw ought to play within the screw DE, and be connected with the screw CD, so as to move round along with it. It must have, according to the foregoing proportions, 111 threads in an inch; and they must lie in a contrary direction to those of CD; so that when they are both turned together, and CD moves upwards, this other may move downwards. At one turn this will move upwards $\frac{1}{111}$ th part of an inch, and at the same time will move in a circular direction; but the accuracy

required in constructing such screws, even though made with fewer threads than those just mentioned, would probably be too great for practice. In many cases, however, screws upon Mr Hunter's principles may be of considerable use.

The theory of the screw is easily deduced from that of the inclined plane and lever; for the threads of the screw in fact form a continued inclined plane, the height of which is the distance betwixt the two threads, and the length is the circumference of the cylinder. Hence, without any lever, the screw would have a considerable power, were it not for the great friction of the parts upon one another; and this friction would be much more increased by the perpendicular action of a weight on the top of the cylinder than by the horizontal action of a lever.

§ 7. Other methods of accumulating power, which do not properly come under the denomination of any of the mechanical powers already described.

FROM the account already given of the six mechanical powers, it is evident, that they can do no more than accumulate, or, if we may use the expression, compress, any degree of velocity into a small space. The velocity thus compressed, becomes what we call power, and is capable of again impressing the original degree of velocity upon a body of an equal or nearly equal size to the first which originally impressed it; but in every case the absolute quantity of motion, or of power, remains the same without a possibility of augmentation or diminution by levers, screws, pulleys, or wedges. It follows, therefore, that if by any method we can preserve for a certain time a small quantity of motion, that will at the end of the time specified amount to an astonishing power, which we could scarce at first have imagined to proceed from so small a cause. Thus, though a man cannot raise a ton weight from the ground at once, he is easily capable of raising 100 pounds at once from the ground, and this for a considerable number of times in succession. It is plain, therefore, that in a very short time a man could in this manner raise the ton weight, if it were divided into 20 parts, as effectually as by a lever or other machine; though the fatigue consequent upon stooping down and raising up his body so often would no doubt make the toil much greater. Even by means of a lever, however, before a man could raise a ton weight one foot from the ground, with the trouble of exerting a force equal to 100 pounds, he must have a lever 20 or 21 feet in length, and exert a constant force of 100 pounds, while he goes up through a space of 20 feet, or pulls down a rope through that space. The lever, therefore, only accumulates the power exerted in pulling or carrying the weight of 100 pounds through 20 feet, and discharges it all upon the space of one foot; whence it is plain, that any other thing which could do this would raise the ton weight as effectually as the lever.

One method of accumulating a great power is by suspending a very heavy body by a chain or strong rope of considerable length. This body may be put in motion by a very small degree of power more than is requisite for bending the rope, and will acquire a vibratory motion like a pendulum; by continuing the impulse as the body returns, it will continually acquire greater and greater force, the arches through which

Mechanical powers.

Mechanical
powers.

it moves becoming continually larger, until at last it might be made to overcome almost any obstacle: and upon this principle the battering rams of old were constructed, the power of which has been already mentioned; nevertheless the power of one stroke of this engine never could exceed the accumulated power of the impulses given to it in order to produce that stroke, or even quite equal it, because the stiffness of the rope, and the resistance of the air, must always take off something from it.

Another method of accumulating force is by means of a very heavy wheel or cylinder, moveable about an axis. A small force will be sufficient to put this wheel in motion; and, if long continued, will accumulate in such a manner as to produce such effects in raising weights and overcoming resistances, as could not by any means be accomplished by the application of the original moving force. On this subject Mr Atwood has demonstrated, that a force of 20 pounds applied for 37 seconds to the circumference of a cylinder of 10 feet radius, and weighing 4713 pounds, would, at the distance of one foot from the centre, give an impulse to a mallet-ball equivalent to what it receives from a full charge of gun-powder. The same effect would be produced in six minutes and ten seconds by a man turning the cylinder with a winch one foot long, in which he constantly exerted a force of 20 pounds. In this case, however, as well as the former, there is not any absolute accumulation of power; for the cylinder has no principle of motion in itself, and cannot have more than it receives.

33
Of the use
of flies in
various ma-
chines.

This accumulation of motion, however, in heavy wheels, is of great service in the construction of machines for various purposes, rendering them greatly more powerful and easy to be worked by animals, as well as more regular and steady, when set in motion by water, or any inanimate power. Hence the use of flies, ballast-wheels, &c. which are commonly supposed to increase the power of a machine, though in reality they take something from it, and act upon a quite different principle.—In all machines in which flies are used, a considerably greater force must at first be applied than what is necessary to move the machine without it, or the fly must have been set in motion some time before it is applied to the machine. It is this superfluous power which is collected by the fly, and serves as a kind of reservoir from which the machine may be supplied when the animal slackens his efforts. This, we must observe, will always be the case with animals, for none are able to exert a great power with absolute constancy; some intervals of rest, even though almost imperceptible, are requisite, otherwise the creature's strength would in a short time be entirely exhausted. When he begins to move the machine he is vigorous, and exerts a great power; in consequence of which he overcomes not only the resistance of the machine itself, but communicates a considerable degree of power to the fly. The machine, when moving, yields for a time to a smaller impulse; during which time the fly itself acts as a moving power, and the animal recovers the strength he had lost. By degrees, however, the motion of the machine decreases, and the animal is obliged to renew his efforts. The velocity of the machine would now be considerably increased, were it not that the fly now

Mechanical
powers.

acts as a resisting power, and the greatest part of the superfluous motion is lodged in it, so that the increase of velocity in the machine is scarcely perceptible. Thus the animal has time to rest himself until the machine again requires an increased impulse, and so on alternately.—The case is the same with a machine moved by water, or by a weight; for tho' the strength of these does not exhaust itself like that of an animal, yet the yielding of the parts of the machine renders the impulse much less after it begins to move: hence its velocity is accelerated for some time, until the impulse becomes so small that the machine requires an increase of power to keep up the necessary motion. Hence the machine slackens its pace, the water meets with more resistance, and of consequence exerts its power more fully, and the machine recovers its velocity. But when a fly is added to the other parts, this acts first as a power of resistance, so that the machine cannot acquire the velocity it would otherwise do. When it next begins to yield to the pressure of the water, and the impulse of course to slacken, the fly communicates part of its motion to the other parts; so that if the machine be well made, there is very little difference in the velocity perceptible.—The truth of what is here advanced will easily be seen, from considering the inequality of motion in a clock when the pendulum is off, and how very regularly it goes when regulated by the pendulum, which here act as a fly.

Flies are particularly useful in any kind of work which is done by alternate strokes, as the lifting of large pebbles, pumping of water, &c. In this case the weight of the wheel employed is a principal object; and the method of calculating this is to compare it with the weight to be raised at each stroke of the machine. Thus, suppose it required to raise a pebble 30 pounds weight to the height of one foot 60 times in a minute: Let the diameter of the fly be seven feet, and suppose the pebble to be lifted once at every revolution of the fly; we must then consider what weight passing through 22 feet in a second will be equivalent to 30 pounds moving through one foot in a second. This will be $30 \div 22$ or $1\frac{1}{2}$ pounds. Were a fly of this kind to be applied, therefore, and the machine set a going, the fly would just be able to lift the pebble once after the moving power was withdrawn; but by increasing the weight of the fly to 10, 12, or 20 pounds, the machine when left to itself would make a considerable number of strokes, and be worked with much less labour than if no fly had been used, though no doubt at the first it would be found a considerable incumbrance to the motion. This is equally applicable to the action of pumps; but the weight which can be most advantageously given to a fly has never yet been determined by mechanics. It is certain, however, that the fly does not communicate any absolute increase of power to the machine; for if a man or other animal is not able to set any mechanical engine in motion without a fly, he will not be able to do it though a fly be applied, nor will he be able to keep it in motion though set a-going with a fly by means of a greater power. This may seem to be contradicted by the example of a common clock; for if the pendulum be once stopped, the weight is not able to set it in motion again, though it will keep it going when once put in motion by an external power. This, however, depends

Mechanical Powers.

depends not upon any insufficiency of the weight, but on the particular mechanism of the crown wheel; which is such, that when once the pendulum is stopped, it would require a much greater weight than that commonly applied to set it in motion; and if the usual weight was to act fairly, it would be more than sufficient to move all the machinery, and make the pendulum vibrate also with much greater force than it does.

§ 8. Of Friction.

THE doctrine of friction, according to Mr Ferguson, may be summed up in the following manner: 1. When one body insits on another upon a horizontal plane, it presses it with its whole weight; which being equally reacted on, and consequently the whole effect of its gravity destroyed by the plane, it will be absolutely free to move in any horizontal direction by any the least power applied thereto, provided both the touching surfaces be perfectly smooth. 2. But since we find no such thing as perfect smoothness in the surfaces of bodies, but an evident roughness or unevenness of the parts in their surface, arising from their porosity and peculiar texture, it is easy to understand, that, when two such surfaces come together, the prominent parts of one will in some measure fall into the concave parts of the other; and therefore, when an horizontal motion is attempted in one, the fixed prominent parts of the other will give more or less resistance to the moving surface, by holding and detaining its parts; and this is what we call *friction*. 3. Now since any body will require a force proportional to its weight to draw it over a given obstacle, it follows, that the friction arising to the moving body will always be in proportion to its weight only, and not the quantity of the surface by which it bears upon the resisting plane or surface. Thus, if a piece of wood four inches wide and one thick be laid upon another fixed piece of the same wood, it will require the same weight to draw it along, whether it be laid on its broad or narrow side. 4. For though there be four times the number of touching particles on the broad side (*ceteris paribus*), yet each particle is pressed with but $\frac{1}{4}$ th of the weight that those are on the narrow side; and since four times the number, multiplied by $\frac{1}{4}$ th of the weight, is equal to $\frac{1}{4}$ th of the number multiplied by four times the weight, it is plain the resistance is equal in both cases, and so requires the same force to overcome it. 5. The reason why friction is proportional to the weight of the moving body is, because the power applied to move the body must raise it over the prominent parts of the surface on which it is drawn; and this motion of the body, as it is not upright, so it will not require a power equal to its whole weight; but being in the nature of the motion on an inclined plane, it will require only a part of its own weight, which will vary with the various degrees of smoothness and asperity. 6. It is found by experiment, that a body will be drawn along by nearly $\frac{1}{4}$ d of its weight; and if the surfaces be hard and well polished, by less than a third part; whereas if the parts be soft or ragged, it will require a much greater weight. Thus also the cylinder of wood AB, if very smooth, and laid on two well polished supports CD (having been first oiled or greased), and

then charged with the weight of two pounds in the two equal balls GH, it will require an additional weight x , equal to about a third part of the two pounds, to give motion to or overcome the friction of the said cylinder. 7. Now this additional weight, as it causes a greater weight of the cylinder, will likewise increase the friction; and therefore require the addition of another weight y , equal to the third part of its own weight; for the same reason, the weight y will require another z , a third part less; and so on *ad infinitum*. Hence, supposing the friction to be precisely a third of the weight, the first weight with all the additional ones, *viz.* $2, \frac{2}{3}, \frac{2}{9}, \frac{2}{27}$, &c. will be a series of numbers in geometrical progression decreasing. Now the sum of all these terms, except the first, is found, by a well-known theorem in arithmetic, to be equal to one pound. So that if the weight of the cylinder be inconsiderable, the readiest way to overcome the friction would be to double the power G, or H, at once. 8. But though we may, at a medium, allow a third part of the weight with which any simple machine is charged for the friction arising from thence, yet this is very precarious, and seldom is the case: for if ABCD be a piece of brass of six ounces, and EFGH be also a plate of brass, and both the surfaces well ground and polished, the weight P of near two ounces will be required to draw along the body AC alone; but if AC be loaded with 6, 8, or 10 lb. then a sixth part of the weight will be sufficient to draw it along the plane. On the other hand, if the plane be covered with a linen or woollen cloth, then a third or half part, and sometimes more, will be requisite to draw it along on the plane. 9. Yet notwithstanding the difficulty and uncertainty attending the estimation of the quantity of friction, it is still a most useful and necessary inquiry, how and by what means the friction of any machine may be diminished? In order to this, we must consider friction mechanically, or as a force acting against a power applied to overcome it. Thus suppose AB an upright stem Fig. 56. or shaft, turning freely in the socket B fixed in the table or plane IKLM; and AC, DE, two arms fixed in the said shaft, the latter of which, DE, has three pins going into a socket in the middle of heavy weights, F, G, or H, in such a manner, that when a power applied at C moves the lever AC, it causes the lever DE to protrude or thrust along the weights at F, G, or H, in a circular manner upon the table. 10. Now since we suppose the weight, all the while it is in motion, is freely and wholly supported by the plane, it follows, that all the resistance it can give to the power applied to C, is only what arises from its friction on the plane. What this friction is, will be found by applying the weight at G, so that BG be equal to AC; for then the power applied to C, acting in a tangent to the circle CRS, that shall just move the weight G, will be equal to its friction. But if the weight be applied at F, because BF is greater than AC, the same power at C, as before, will not move it, by reason its force is here increased, by having a greater velocity than the power; as, on the other hand, if placed at H, a less power at C shall move it, because of its having there less velocity than the power, as is evident from the properties of the lever. 11. Hence we understand, that though the

54.

Mechanical
Powers

weight of a machine remains the same; yet the friction may be diminished, by contriving that the parts on which it moves and rubs shall have less velocity than the power which moves it: thus, if the cylinder AB (fig. 54.) were to move on the two small pins or gudgeons E, F, the friction would be abated in the proportion of the diameter of the cylinder to that of the pins. 12. The friction on these gudgeons is still farther diminished by causing them to move on the circumference of a wheel: thus, let F be the gudgeon of the cylinder, revolving on the wheel CDE (fig. 57.), the velocity of the wheel's circumference will be the same with that of the gudgeon; but the velocity of the wheel's axis AB (which is now to be considered as the rubbing part) is less than that of the wheel, in proportion as its diameter is less than that of the wheel: for example, if the friction of the cylinder moving on its surface be $\frac{1}{4}$ part of the weight, and the gudgeon be to the cylinder as 1 : 10, they will reduce the friction to $\frac{1}{40}$ th part; and if, again, the axis of the wheel be to the wheel as 1 : 10, the wheel will reduce the friction to $\frac{1}{400}$ th part; and if the axis of this wheel be laid on the perimeter of another wheel, the friction will be reduced to a still lesser part of the weight; so that you may proceed in this manner to diminish the friction *ad infinitum*; and wheels applied in this manner are called *friction-wheels*. 13. Besides what has been already said, somewhat farther is necessary to diminish the friction of wheel-carriages. It was before observed, that friction arose chiefly by lifting the body over the prominent parts of the plane on which it is moved: now if we can contrive to move the body along without lifting or sustaining its weight, we shall move it without much friction; and this may be done by laying the body on any moveable circular subject, as rollers, wheels, &c.: because the asperities of its surface will lay hold on those of the roller, and move it likewise; and it is as evident, that when the body is drawn against the prominent parts of the roller, they immediately give way, and make no resistance. By this circular motion of the roller, its prominent parts below do only descend and move upon or over, and are not drawn against, the fixed prominent parts of the plane, and so receive no resistance from them. Hence the body is conveyed along without being lifted up, in the same manner as a wheel is moved by a pinion without any considerable resistance.

SECT. III. Of the Combinations of the Mechanical Powers.

FROM what has been already laid down concerning the mechanical powers in particular, we have seen that none of them is capable of augmenting the absolute force of any acting substance; and from thence we may justly conclude, that no combination of them can do so. In fact, these combinations are very often detrimental, and occasion a great loss of power by friction. This is the great obstacle in mechanics, and must always be greater in complex than in simple machines; and therefore the latter are always to be preferred, excepting where convenience requires some degree of complication. The lever being the simplest machine, and that attended with least friction, is always to be

used where it is requisite to raise weights for a small way. It may likewise be used with propriety where bodies are to undergo a long continued degree of pressure, and where they yield but little. For this purpose the lever ought to be of the second kind, represented fig. 28. where one end being fixed at A, a weight may be put upon the other extremity B, and the body to be pressed put at 1, 2, or any of the intermediate divisions, according to the degree of pressure it is designed to undergo. This has the advantage of giving a long and very equable pressure, and is a very advantageous method of pressing cheese or other things which do not require a very great exertion of force. Where this is requisite we must employ wedges or screws; but both these have the disadvantage of slackening their pressure on the least yielding of the materials to be pressed. Wedges therefore require to be almost constantly driven, and screws to be turned by a lever, in order to produce a constant pressure. In oil-mills the pressure is produced by wedges, which are constantly driven by great mallets lifted up by the force of the mill. Oil of sweet almonds is made by apothecaries in a press driven by a screw, and turned by a long lever assisted by a capstan.

Where it is necessary to have a considerable weight raised to some height, the pulley is the most useful power, but the friction is extremely great; the axis in peritrochio combined with a single pulley will answer the purpose extremely well, and with less friction than any machine composed of pulleys alone. The best method of constructing cranes is these two; and are very much used, especially by the commercial people, for raising goods out of ships, drawing them up into warehouses, and for lowering them down. In these operations we must observe, that lowering goods is much more dangerous than raising them, on account of the vast increase of velocity which bodies acquire every moment by the power of gravity. In the construction of cranes, therefore, it is absolutely necessary to attend to this circumstance, and to guard against accidents. The following are recommended by Mr. Ferguson: Fig. 32. shows one crane well calculated for the purposes just mentioned. When the rope H is hooked to the weight K, a man turns the winch A, on the axis whereof is the trundle B, which turns the wheel C, on whose axis D is the trundle E, which turns the wheel F with its upright axis G, on which the great rope HH winds as the wheel turns; and going over a pulley I, at the end of the arm d of the gib cde, it draws up the heavy burden K; which being raised to a proper height, as from a ship to the quay, is then brought over the quay by pulling the wheel Z round by the handles x, z, which turns the gib by means of the half wheel b fixed on the gib-post ce, and the strong pinion a fixed on the axis of the wheel Z. This wheel gives the man that turns it an absolute command over the gib, so as to prevent it from taking any unlucky swing, which so often happens when it is only guided by a rope tied to its arm d; and people are frequently hurt, sometimes killed, by such accidents.

The great rope goes between two upright rollers i and k, which turn upon gudgeons in the fixed beams f and g; and as the gib is turned towards either side, the rope bends upon the roller next that side. Were

it not for these rollers, the gib would be quite unmanageable; for the moment it were turned ever so little towards any side, the weight K would begin to descend, because the rope would be shortened between the pulley I and axis G; and so the gib would be pulled violently to that side, and either be broken to pieces or break every thing that came in its way. These rollers must be placed so that the sides of them round which the rope bends may keep the middle of the bended part directly even with the centre of the hole in which the upper gudgeon of the gib turns in the beam *f*. The truer these rollers are placed, the easier the gib is managed, and the less apt to swing either way by the force of the weight K.

A ratchet-wheel Q is fixed upon the axis D, near the trundle E; and into this wheel falls the catch or click R. This hinders the machine from running back by the weight of the burden K, if the man who raises it should happen to be careless, and to leave off working at the winch A sooner than he ought to do.

When the burden K is raised to its proper height from the ship, and brought over the quay by turning the gib about, it is let down gently upon the quay, or into a cart standing thereon, in the following manner: A man takes hold of the rope *h* (which goes over the pulley *v*, and is tied to a hook at S in the catch R), and so disengages the catch from the ratchet-wheel Q; and then, the man at the winch A turns it backward, and lets down the weight K. But if the weight pulls too hard against this man, another lays hold of the handle V, and by pulling it downward draws the gripe U close to the wheel Y, which by rubbing hard against the gripe hinders the too quick descent of the weight; and not only so, but even stops it at any time if required. By this means, heavy goods may be either raised or let down at pleasure, without any danger of hurting the men who work the engine.

When part of the goods are craned up, and the rope is to be let down for more, the catch R is first disengaged from the ratchet-wheel Q, by pulling the cord *t*; then the handle *g* is turned half round backward, which, by the crank *nn* in the piece *o*, pulls down the frame *b* between the guides *m* and *m* (in which it slides in a groove), and so disengages the trundle B from the wheel C; and then the heavy hook *β* at the end of the rope H descends by its own weight, and turns back the great wheel F with its trundle E and the wheel C; and this last wheel acts like a fly against the wheel F and hook *β*, and so hinders it from going down too quick; whilst the weight X keeps up the gripe U from rubbing against the wheel Y, by means of a cord going from the weight over the pulley *w* to the hook W in the gripe; so that the gripe never touches the wheel unless it be pulled down by the handle V.

When the crane is to be set at work again for drawing up another burden, the handle *g* is turned half round forwards; which, by the crank *nn*, raises up the frame *b*, and causes the trundle B to lay hold of the wheel C; and then, by turning the winch A, the burden of goods K is drawn up as before.

The crank *nn* turns pretty stiff in the mortise near *o*, goes against the farther end of it when it has got just a little beyond the perpendicular; so that it can never come back of itself: and therefore the

trundle B can never come away from the wheel C until the handle *g* be turned half round.

The great rope runs upon rollers *pp* in the lever LM, which keep it from bending between the axle at G and the pulley I. This lever turns upon the axis N by means of the weight O, which is just sufficient to keep its end L up to the rope; so that, as the great axle turns, and the rope coils round it, the lever rises with the rope, and prevents the coils from going over one another.

The power of this crane may be estimated thus: Suppose the trundle B to have 13 flaves or rounds, and the wheel C to have 78 spur-cogs; the trundle E to have 14 flaves, and the wheel F 56 cogs: then, by multiplying the flaves of the trundles, 13 and 14, into one another, their product will be 182; and by multiplying the cogs of the wheels, 78 and 56, into one another, their product will be 4368; and dividing 4368 by 182, the quotient will be 24: which shows that the winch A makes 24 turns for one turn of the wheel F and its axle G, on which the great rope or chain HHH winds. So that if the length or radius of the winch A were only equal to half the diameter of the great axle G, added to half the thickness of the rope H, the power of the crane would be as 24 to 1: but the radius of the winch being double the above length, it doubles the said power, and so makes it as 48 to 1: in which case, a man may raise 48 times as much weight by this engine as he could do by his natural strength without it, making proper allowance for the friction of the working parts. Two men may work at once, by having another winch on the opposite end of the axis of the trundle under B, and so make the power still double.

If this power be thought greater than what may be generally wanted, the wheels may be made with fewer cogs in proportion to the flaves in the trundles; and so the power may be of whatever degree is judged to be requisite. But if the weight be so great as will require yet more power to raise it (suppose a double quantity), then the rope H may be put under a moveable pulley, as *z*, and the end of it tied to a hook in the gib at *i*; which will give a double power to the machine, and so raise a double weight hooked to the block of the moveable pulley.

When only small burdens are so raised, this may be quickly done by men pushing the axle G round by the handspokes *y, y, y*; having first disengaged the trundle B from the wheel C: and then, this wheel will only act as a fly upon the wheel F; and the catch R will prevent its running back, if the men should inadvertently leave off pulling before the burden be unhooked from *β*.

Lastly, when very heavy burdens are to be raised, which might endanger the breaking of the cogs in the wheel F; their force against these cogs may be much abated by men pushing round the handspokes *y, y, y, y*, whilst the man at A turns the winch.

We have only shewn the working parts of this crane, without the whole of the beams which support them; knowing that these are easily supposed, and that if they had been drawn, they would have had a great deal of the working parts from sight, and also confused the figure.

Another very good crane is made in the following manner:

manner : AA (fig. 53) is a great wheel turned by men walking within it at H. On the part C, of its axle BC, the great rope D is wound as the wheel turns; and this rope draws up goods in the same way as the rope HH does in the above-mentioned crane, the gib-work here being supposed to be of the same sort. But these cranes are very dangerous to the men in the wheel; for if any of the men should chance to fall, the burden will make the wheel run back and throw them all about within it; which often breaks their limbs, and sometimes kills them. The late ingenious Mr Padmore of Bristol (whose contrivance the fore-mentioned crane is), observing this dangerous construction, contrived a method for remedying it, by putting cogs all around the outside of the wheel, and applying a trundle I to turn it; which increases the power as much as the number of cogs in the wheel is greater than the number of flaves in the trundle: and by putting a ratchet-wheel F on the axis of the trundle (as in the above-mentioned crane), with a catch to fall into it, the great wheel is stopped from running back by the force of the weight, even if all the men in it should leave off walking. And by one man working at the winch I, or two men at the opposite winches when needful, the men in the wheel are much assisted, and much greater weights are raised, than could be by men only within the wheel. Mr Padmore put also a gripe-wheel G upon the axis of the trundle, which being pinched in the same manner as described in the former crane, heavy burdens may be let down without the least danger. And before this contrivance, the lowering of goods was always attended with the utmost danger to the men in the wheel; as every one must be sensible of who has seen such engines at work. And it is surprising that the masters of wharfs and cranes should be so regardless of the limbs, or even lives of their workmen, that, excepting the late Sir James Creed of Greenwich, and some gentlemen at Bristol, there is scarce an instance of any who has used this safe contrivance.

We shall describe here four new cranes invented and made by Mr Gottlieb of Hounsditch, London, who communicates them to the public as quite new in their principles, and more simple and useful than any hitherto contrived. Fig. 59. is a representation of a crane adapted for a large warehouse, where heavy goods are wanted to be drawn up from a cart or quay. One of this construction has lately been erected in Mr Camden's sugar-house, Old Gravel-Lane, London. Its operation is as follows: The horse yoked below at A turns the upright axis and the wheel B, which is about 6 feet in diameter; this turns a 3 feet wheel C, having an upright axis D through the floor turning with it, and carrying a 3 feet wheel E with perpendicular cogs. The wheel E turns two pinions F and G, the former of 8 inches in diameter, and the latter of 5 inches diameter, both fixed upon one axis. The pinion G turns a 3 feet wheel H, to which is fixed the barrel I and wheel W. The rope K winds round the barrel, and comes over the sheif-wheel L in the upper story, and the pulley M in the gib-head drawing up the goods suspended at the hook N.

By a mark made upon the rope at I, the man superintending the crane knows when the goods are raised enough for landing into the room: he then imme-

diately pushes aside the upright piece O, disengages the lever P from it; and by putting it downwards, the action of the quarter pinion at Q raises up the pinion at G; and thereby unconnects it with the wheel H. To prevent the machinery now from running backwards, a ratchet-wheel R is fixed upon the wheel H, into which a click-catch S falls. This effectually prevents the wheels going backwards by the weight at N while the man above is employed in landing the goods. When the goods are brought into the store-room, the hook N is thrown out, and the man below, from the usual call, runs to the handle U, slides the pinion T into the wheel H, then turns back the ratchet-wheel R, and pushes back the click S, then slides back again the pinion T; and the wheel H and barrel I being thus at liberty, the hook N and rope run down by their own gravity, and fresh goods are attached; then again, from the usual call, the man pushes up the lever P, fixes it at O, places the click S into the teeth of the ratchet-wheel; and the whole machinery is again in action from the horse below, that keeps constantly going without being stopped at every short interval of the landing, storing, &c.

When the goods are to be carted off, and required to be let down only, it is performed without the horse, and in the following manner: The pinion G is disengaged from the wheel H by the lever P as before, and the pinion V of the fly-wheel is slipped into the teeth of the 2 feet wheel W. The goods being suspended at N, will act by the rope upon the wheel W and pinion V, thereby turning round the fly-wheel X: while the goods are thus descending, the man presses upon the lever Y, and bears against the wheel, making such a resistance as to be sufficient to allow the goods to descend with as gentle a degree of motion as may be necessary.

The hook N being taken from the goods, the man goes to the wheel W, and with his hands turns it round, which winds up the cord and hook in readiness for more goods, and so on as before. The pinions T and V in this case are slipped out of the wheels H and W.

As the horse at A may likewise be used to turn other mill-work from a connection made with the main-wheel, and supposing that the crane is not wanted at the same time, it is readily disengaged by turning of the winch at Z; which, by the pinion A below, working into the teeth of the bar, and the wheel C which turns upon it, quite unconnects the wheel C from the crane.

It is therefore evident from what has been described, that this crane can be managed by two men only, and occasionally without a horse, when very heavy goods are not raised. All the necessary beams for fixing the machinery by, could not be represented in the figure without obscurity and confusion; but these being omitted, will not to the most ordinary mechanic render the general construction of the crane difficult to understand.

A new portable cellar crane is represented in fig. 60. New cellar crane. This is very useful to wine-merchants, brewers, &c. in drawing up and letting down casks full of wine, beer, &c. It saves the trouble and inconvenience of horses, and in many places can be used where horses could not. AA are two wooden props about 6 feet in height, and

Fig. 59.*Fig. 60.**Fig. 61.**Fig. 62.*

Combina-
tion of Me-
chanical
Powers.

and joined together like a ruler at E. They are connected to each other by an iron round bar C and wooden bar at the bottom D. The iron prongs EE fasten the uprights steadily to the edge of the cellar; F is the axis round which two ropes are coiled, the ends of which are fastened to the two clamps GG. On the axis F is fixed the iron wheel H of 3 feet in diameter: in the teeth of this works the pinion I of about 6 or 7 inches in diameter, and is turned by the handle at K.

It is evident, by a bare inspection of the figure, that when the two ropes are slipped over the ends upon the barrel, either at the top or bottom of the cellar, that by turning of the winch K to wards or from you, the barrel can be safely and expeditiously taken out or lowered down.

When the crane is done with, it shuts up by unfreing the nut at B, taking the wheel and axis away out of the loops at L, and folding the sides at A together like a jointed rule; it may then be taken away in the cart or dray, or taken in the mens hands.

Fig. 61. represents a portable stone-crane mounted in a wooden frame and stage, which is judged to be very useful for loading and unloading carts with large heavy stones. It is moveable to any part of a stone-yard or ground; the frame is sufficiently wide for a cart to draw under the crane, and at any time it may be taken to pieces.

The frame AAAA is made of wood, is about 9 or 10 feet high, and about 9 feet square. The wheels BB are of iron, and are about 3 feet in diameter, and the pinion D, that is fixed to the axis of the first wheel B, 8 inches in diameter, on the axis of the second wheel B, the axis round which the rope-coils is fixed.

Now the stones being corded and hooked at the end of the rope, it is very evident that the man at C will either raise or lower them as may be necessary, according as he turns the winch towards or from him, and in a safe and very easy manner.

Fig. 62. is a representation of a crane-carriage which Mr Gottlieb conceives to be very useful in moving large stones in quarries, where carts and horses cannot be conveniently or at all managed. Its principle is evidently clear from a bare view of the figure. It consists only of two sets of crane-wheels applied to the two sets of wheels belonging to the carriage; so that two men, one at each wheel AA, turning the pinions and wheels round, shall act upon the carriage-wheels and move it along. By their both turning forwards or backwards, the carriage goes accordingly; but if they turn contrary ways, the carriage will be turned round, or partly so, as may be wanted.

The pinion B is 6 inches in diameter, which turns the wheel C of 3 feet diameter, on the axis of which is fixed the pinion D of 1 foot diameter, which works into 2 wheels E, E, of 3 feet 6 inches diameter, that are fixed upon the carriage-wheels, and give motion to the whole machine.

The friction of the axle-trees of these machines may be considerably diminished, by applying an improved axle-tree invented by Mr Gottlieb, which he calls the *anti-attrition axle-tree*, and for which he has a patent. It is formed from a steel-roller, from 4 to 6 inches

long, turning within a groove cut in the iron part of the axle; and the advantages discovered by experiments made by Mr Gottlieb will be seen by the small table subjoined. A section of this axle-tree is represented in fig. 65, where *a* is the axle-tree, *b* the groove, *c* the roller, *d* the cavity between the lower part of the tree and the box *e*. In figs. 66, 67, *f* represents the oil-veffel supplying it with oil, *g* the tube to convey the oil by, *h* the straps of ditto, *i* the fastening screws. Figs. 63, 64, give a side view of the axle.

One general maxim to be kept in mind by all mechanics is, that whatever a machine gains in power it loses in time, even supposing friction were entirely out of the question. It must likewise be remembered, that in almost all cases where a machine gains by complication, it will lose one third by mere friction, unless its parts are made with an accuracy not to be expected. In some cases, however, a great power must be had; and in these we must have recourse to the most simple machines, which will lose only time, and but little power by friction; for the complicated ones waste both time and power to a great degree. There is not perhaps a better method of procuring a very great power than by combining a screw with a toothed wheel which acts as an axis in peritrochio, as is represented fig. 50; for by making the threads of the screw pretty close, and the diameter of the wheel large, we may increase the power almost to any degree we please, without any considerable increase of friction. In this case, where it can conveniently be done, it is better to increase the diameter of the wheel than to add another, for this augments the power without any sensible augmentation of the friction; and it is absolutely necessary to have the axle as small as can be made of sufficient strength to bear the weight. Archimedes is said to have boasted, that he could move the earth provided he could find a place to stand on; and Bishop Wilkins, that he could pull the strongest oaks up by the roots by means of a single horse-hair. But abstracting from the impossibility in the case of Archimedes, it does not appear that the bishop could more easily have fulfilled his talk, on account of the immense friction of the machine he must have employed, and the stiffness of the great ropes which must have been bent in order to accomplish his purpose. To perform feats of this kind, a lever seems more likely than any thing; but the vast room it takes up, and the excessive length requisite to make it act with sufficient force, together with the vast weight it must necessarily have if made of the requisite strength, must easily convince us that all such extravagant boasts are vain, and that wherever great effects are to be accomplished, a great power must originally be applied.

Wheel-carriages.

SECT. IV. Of Wheel-carriages.

Wheel-carriages.

41
Sledges
used before
wheel-carriages.

Wheel-carriages in general signify all kinds of machines furnished with wheels, for drawing great weights by means of the strength of animals or otherwise.

It is very probable, that in the infancy of the arts, sledges were used before wheels were invented, or at least before the application of them became very general. Homer mentions them as employed in bringing wood for the funeral of Patroclus; though it is not to be doubted that the Greeks at that time were acquainted with the use of wheels, as the same poet mentions them on all occasions when speaking of the war chariots of his heroes. It is possible, therefore, that by the country people, for inferior purposes, the sledge might be employed, while wheel-carriages were confined to those of superior rank, or used only for war-chariots. It is not long ago indeed since sledges were used for certain purposes in our own country, notwithstanding the number of wheel-carriages used in it from time immemorial. In some of the cold countries, where ice is met with in great quantity, and the ground is covered with frozen snow for a great part of the year, sledges are still used, and run upon the smooth surfaces of these bodies with as great ease as wheels run upon the ordinary ground. Upon very smooth ice, indeed, or upon any body perfectly smooth, wheels would not turn at all; for the only reason why they turn in the ordinary way, is the continual inequality they meet with. If we suppose the wheels to be carried in the air, it is plain that they would not turn, there being nothing to put any part in motion more than another; and the same would be the case if we could suppose ice, or any other body, to be so smooth that it would give as little resistance as air. On common roads, however, the wheels meet with obstructions at the bottom, which retard that part; and in consequence of this the upper part moves forward, and a circulating motion immediately begins to take place. By means of this circulatory motion the friction becomes very much less than what it would be if the weight were drawn along the ground upon a sledge, inasmuch that, according to the computation of Dr Hellsham, a four-wheeled carriage may be drawn with five times as much ease as one that slides upon the same surface as a sledge.

42
Obstacles
which occur
to the motion of
carriages.

The structure of wheel-carriages is so generally known, that it is needless to describe them. In the construction of them, however, there are several particulars to be observed, which may render one method of construction preferable to another, though there may be a general similarity between one carriage and another. In order to ascertain the most proper method for constructing them, it will first be necessary to consider the obstacles which occur to their motion. These are,

1. The *vis inertia* of matter.—This, though for a considerable time supposed to be a principle of mere *inactivity*, or *resistance* to any change of state from motion to rest in material bodies, is now almost exploded. Mr Antice, in a late treatise on wheel-carriages, supposes the philosophers who maintain the existence of such a principle, to have mistaken Sir Isaac Newton and other great men. According to him, they meant no more by the *vis inertia* of matter than a mere passiveness in it, by which it was disposed to abide

in that state, either of rest or motion, in which it originally was; “whereby it alters not its state but in proportion to the quantity of power exerted against it. Thus, should a body of any given weight or quantity of matter, moving with a certain degree of velocity, strike another body at rest of the same weight, it would communicate half its motion to that body, and they would move together with the same velocity as the first; but this proceeds from no principle of the body at rest to resist motion, it does not destroy in the other more than it receives from it; therefore no motion is lost, it is only divided; and the two after division have a power equal to that of the one before it, with the whole velocity of motion. Indeed when we consider that the least degree of motion in any body, however small, will communicate some degree of it to the largest in the universe; and that, on the contrary, none but an equal degree of impetus can deprive a body of actual motion, and that immediately opposed to it: add to this, that since all matter within the reach of our observation, and by analogy we have reason to think it is in actual and rapid motion, impressed on it by its great Creator, and co-existent with it; we may conclude, that if matter do not affect, it is more liable to motion than to rest.”

2. *Friction*. By this is meant the quantity of motion destroyed by bodies sliding over one another, and which is in proportion to the weights laid upon them. See Sect. II. § 8.

Friction depends not only upon the pressure made on the moving bodies, but on the inequalities on the surfaces upon which they move. For as the surfaces of even the most highly polished bodies have some inequalities, whenever two of them are pressed together, the inequalities of the one must enter, and in some degree accommodate themselves, to those of the other; and as the forms of these inequalities are of infinite variety, it is impossible to give any general description which can exactly answer to every one of them.

Mr Antice supposes the varieties only to be of two kinds, which he thinks may not be very dissimilar to any that occur. 1. Let us imagine two sliding surfaces, when viewed through a microscope, to present such an appearance as is represented in fig. 69. in which A is the sliding body to be moved in the direction CD over the fixed body B. To erect this, it is evident, that either the teeth must be violently broken off, or a power applied to them sufficient to make them slide upon each other on the principles of the inclined plane; in which case the friction must always be in proportion to the weight of the slider, and that with which it is loaded, without regard to the length or breadth of the bearing surface: for if only one pound rested upon one tooth, there would be no more but that pound to be lifted. If the pound rested upon two teeth, there would only be half a pound to be lifted over each, and so on to any number; but if we suppose the teeth to be of such a shape, that they cannot act as inclined planes, let them be ever so strong, we must calculate the friction in a different manner.

Let surfaces of this kind be represented by fig. 70. In which case it is evident, that instead of depending on the weight or pressure only, it will be in proportion to the number and strength of the teeth so lock-

Plate
CCLXXXV

ed together; or, in other words, on the length and breadth of the rubbing surfaces. On this supposition the weight of the slider will have little or no effect in breaking the teeth, or hindering its being done by the power applied in the longitudinal direction; but if one tooth is to be broken, it will be necessary to apply twice that power to break two, thrice the power to break three, &c. Hence it is evidently impossible to form any general rule concerning the friction which takes place on this principle. As experience, however, has shown that two bricks, or other bodies of that kind, are almost as easily drawn along a table when placed side by side, as when laid upon each other, it seems probable that such a locking of parts seldom occurs; and when it does, the obstacles are soon broken down. Yet it is certain, that some such thing must take place on all occasions, otherwise the wearing of bodies which rub upon one another could not happen.

From what has been said it must appear plain, that if a slider be laid upon an horizontal plane, it must remain at rest; though by a very small force, such as is barely sufficient to overcome the friction, it will be set in motion: because, on a plane quite horizontal, the motion of any body does not remove it in the least farther from the point to which it is attracted by the force of gravity. If the plane be inclined to the horizon, then, besides the power necessary to overcome the friction, it will be necessary to have one sufficient also to overcome that of gravity, by which it is determined to roll down the plane; the proportion of which is ascertained under Sect. II. § 4. The difficulty of raising great weights in this manner, however, where the ascent is steep, and the ways rough, must necessarily be so great, that sledges could not be used with any advantage, and therefore wheels are indispensable.

The advantage of wheels over sledges may be further understood from the following considerations. 1. A sledge, in sliding over a plane, suffers a friction equivalent to the distance through which it moves; but if we apply to it an axle, the circumference of which is six inches, and that of the wheels eighteen feet, it is plain, that moving the carriage eighteen feet over the plane, the wheels will make but one revolution; and as there is no sliding of parts between the plane and the wheels but only a mere change of surface, no friction can take place there, the whole being transferred to the nave acting on the axle, so that the only sliding of parts has been betwixt the inside of the nave and the axle; which, if they fit one another exactly, is no more than six inches: and hence it is plain, that the friction must be reduced in the proportion of one to thirty-six. Another advantage is also gained, by having the surfaces confined to such a small extent; by which means they may be more easily kept smooth, and fitted to each other. The only inconvenience is the height of the wheel, which must in all cases be added to that of the carriage itself.

It has been a matter of no little consideration, whether the wheels of a carriage ought to be small or large; and this subject Mr Antice has treated in a very particular manner. He observes, that in the overcoming of such obstacles as are commonly met with in roads, wheels act as mechanical powers, and therefore the size of the wheel must be regulated upon the

principles of these powers. Thus, let the circle O T A G L, fig. 71, represent a wheel of four feet diameter, placed on the level P Q, and opposed in that line by the obstacle O, which is supposed to be 7.03 inches in height; the line in which the carriage is drawn being C T, parallel to the plane P Q. In this case the effort applied to the carriage is communicated to the nave of the wheel where it touches the axle. This part, therefore, represents the part of the lever to which the power is applied, and is the point C in the figure. As the turning point is that where the wheel touches the obstacle, that must represent the fulcrum of the lever; whence that arm of the lever will be represented by CO, which may be supposed a spoke of the wheel: and as the upright spoke C L is in the line which bears the whole weight from the axle, and in which it is to be lifted; hence that part of the circumference of the wheel which is between the fulcrum and the upright spoke bearing on it, must represent the arm of the lever which is to raise the weight. In this case neither the weight nor the power act at right angles to their respective arms of the lever; so that we must represent their powers by the imaginary lines MO and ON. As the length of OM, therefore, is to that of ON; so is the proportion required to the weight to balance it on the obstacle, when rising over it; and in this case the arms are equal, it is plain that the powers must be so likewise. Every obstacle, therefore, exceeding this height, which is as 7.03 to 48, will require a power acting parallel to the plane greater than the weight drawn; and every obstacle whose height bears a smaller proportion to that of the nave, must be overcome by a smaller power.

Again, let a wheel of four feet diameter be represented by the circle in fig. 72, and supposed to be moved along the plane P Q, and an obstacle of twelve inches height be placed before it, the real lever will then be represented by the lines L O C; which being reduced to the imaginary ones MON, shows that the power is greater than the weight. By the same rule, if an obstacle of three inches be placed in the way of a wheel, as in fig. 73, the power required to move the wheel will be considerably less than the weight, though it is plain that the proportion of power must always be according to the size of the wheel, the height of the obstacle, and the direction in which the carriage is drawn. For instance, if the line of traction in fig. 73, be raised into the direction CS, the power required to move the carriage over it will be to the real weight as the line CO is to the line ON; and in consequence of thus altering the direction, we gain as much as the length of the line CO exceeds that of CN.

This view of the manner in which the wheels of carriages act, will serve to elucidate the question, whether large or small wheels are preferable for carriages? Let the circle fig. 74. represent a wheel of two feet diameter, and the obstacle in its way 7.03 inches in height; then will the true lever be represented by the lines COL, to be reduced to the imaginary ones MON. In this case, the power required to draw the carriage must be to its weight as NO is to OM, which is more than double; and thus the advantage of large wheels over small ones is evident. In this, however, as in all other cases, where wheels act as mechanical

Wheel-carriages.

431
whether
large or
small
wheels are
preferable.

Wheel-
carriages.

nical powers, we must remember, that the same doctrine applies to them as to the powers themselves when used in any other manner, viz. that as much as we gain in power we lose in time; and therefore, though a wheel of twice the diameter may be raised over an obstacle of any given height with twice the ease that would be required for one of once the diameter, yet the large wheel would require twice the time to move over it that the small one does.

Hitherto we have considered the carriage as being drawn in a direction parallel, or nearly so, to the plane on which the wheels move, which line is supposed to be horizontal; but the case will be different when we suppose them to move upon an inclined plane; for then, even though the line of traction be parallel to the ascending plane, and though the wheels act as levers, we shall find that the action of the weight will increase with the power gained by the increase of size in the wheels; and consequently, that the increased size of the latter will be of no farther use than that of diminishing the friction, in the same manner as is done upon horizontal planes.

To illustrate this, suppose the larger circle in fig. 75. to represent a wheel of four feet diameter, and the smaller circle a wheel of only two, both of which are made to ascend the inclined plane LM, by powers applied in the directions GI and ES parallel to the elevation of the plane, which is 45 degrees; it will then be found, that by describing the lever as in the former case, though the arm of the lever to which the power is applied be double the length in the large wheel that it is in the small, the other is augmented in the same proportion. Neither will the powers be augmented by varying the direction of the line of traction; for while these are kept parallel to one another, their relative powers must always keep the same proportion to one another. The reason is obvious, viz. that when wheels of any dimension ascend or descend inclined planes of any regular elevation, the fulcrum of the lever contained in the wheels must be determined by that part of the wheel which touches the plane, and which must always be of a proportionate height both in large and small wheels. It is otherwise, however, with the fulcrum marked out by perpendicular or irregular obstacles upon the plane itself; for large wheels will always have the advantage over small wheels when these are preferred, for the reasons already given. Indeed, when the wheel impinges perpendicularly upon an obstacle as high as the line of traction, it is plain that it cannot be drawn over it by any power whatever, unless the direction of the latter be altered.

From these considerations, our author draws the following conclusions: 1. That in a carriage placed upon an horizontal plane, nothing more is required to produce motion than to overcome the friction which takes place between it and the plane. 2. By the application of wheels to a carriage, the friction is lessened in the proportion of the diameters of the axles and hollow parts of the naves to those of the wheels. 3. In the draught of a carriage without wheels up a regular plain ascent, the friction must not only be overcome, but there is a power likewise to be applied sufficient to lift such a proportion of the weight of the carriage as the perpendicular part of the ascending plane bears to that portion of the plane. 4. If wheels of any size

44
General
conclusions
concerning
the motion
of carriages.

be applied to the carriage in such circumstances, they have only the advantage of lessening the friction; for though they really act as levers, yet as each arm of the lever is lengthened in proportion to the increase of size in the wheels, the power can be no farther augmented than as the ascent may act as a mechanical power for raising up the wheels, carriage, &c. to the top. 5. Large wheels have the advantage over small ones in overcoming obstacles, because they act as levers in proportion to their various sizes. 6. The line of traction, or that in the direction of which the carriage is drawn, should always, if possible, be parallel to that in which the plane lies; for when this is the case, the arm of the lever to which the power is applied will bear the longest proportion possible to the other. This always takes place when the line of traction is perpendicular to that spoke of the wheel which points to the obstacle. As it may not always be possible, however, to alter the direction of the line of traction to this position, it will be most proper to fix upon some medium betwixt that which commonly occurs and that which requires the greatest exertion to overcome the obstacle; that is, betwixt a level line and one rising perpendicular to the spoke of the wheel which points to the obstacle it is likely to meet with. The greater attention ought to be paid to this last, that all wheels, but especially small ones, are liable to sink into the ground over which they pass, and thus produce a constant obstacle to their own progress. The line of traction, it must also be observed, is not an imaginary one drawn from that part of the animal to which the traces or chains are attached to the axle of the wheel, but the real direction of the traces to whatever part of the carriage they are attached; for the effort will be instantly communicated in the same direction from one part of the carriage to all the rest, by reason of the whole being fastened together and in one piece.

Hitherto we have considered the whole weight of the carriages as bearing perpendicularly against the axles of the wheels: but as this cannot be done in chairs, carts, and other carriages having only two wheels, it will be necessary to have their centres, or transverse lines of gravity, as near to the ground as possible. To understand this, it must be premised, that the centre of gravity is that point of any body which if suspended will keep all the parts of the body at rest, let the body be placed in any situation we please. Thus the centre of gravity in a wheel or circle is the centre of the circumference, provided the substance of it be equally ponderous throughout. In like manner, the real centre of a globe coincides with the centre of gravity, provided the matter of which it is composed be equally ponderous. In a square, whether superficial or solid, the centre of gravity will be a point equally distant from all its sides; so that if the substance be equally heavy, it will be impossible to turn it into any position in which there will not be as much matter upon one side of the centre as upon the other: and in like manner, every figure, however irregular, has some point round which, if it be turned, as much matter will always be upon one side as on the other.

If now any body be supported by a transverse line passing not through the centre of gravity itself, but either

Wheel-carriages.

either above or below it, the body can only be kept in equipoise while that line remains directly above or below the point; for if the body is moved forwards, as in two-wheeled carriages moving down hill, a greater part of the weight will be thrown forwards over the line of suspension than what remains behind it; and consequently this superfluous part must be borne by the animal which draws it. In ascending any height, just the reverse takes place; for thus a portion of the weight is thrown backwards, and will tend to lift up the animal altogether. The consequence of this is, not only that the creature must proceed with great pain, but that the friction on the nave and axle will be augmented by laying upon them a part of the animal's weight also. If the body be suspended above the centre of gravity, the effect, though the same in the main, will be reversed in the ascent and descent of hill, as long as the body is firmly attached to the shafts; but should the whole weight be suspended under the axle, independent of the shafts altogether, then it will always, whether ascending, descending, or moving horizontally, have the same effect as if hung directly by it.

45.
Of suspending carriages above or below the centre of gravity.

Our author next proceeds to treat of a generally received opinion, that the disadvantages attending carriages suspended either above or below the centre of gravity are augmented by the height of the wheels. The reason given for this opinion is, that the hinder part of the load in ascending an hill, being thrown back, will overhang that part of a large wheel which touches the plane, much more than when a smaller wheel is used. Mr. Anllie, however, observes, that all the disadvantage, in either case, is expressed by the weight which, from its action upon the axle, tends to lift the animal, which must always be the same whether the wheels are high or low. Thus, in fig. 76. let a carriage be represented with two wheels of four feet diameter, ascending a plane of 35° elevation from the level L E. Let fig. 77. represent a carriage exactly in the same circumstances with the former, only that the wheels are six feet in diameter. Let C be the centre of gravity, and SP the line of gravity parallel to the central line AR, the line of support or suspension; in each of these the body is thrown so far back by its position, that the space GS and AR is taken from before the line of gravity, and added to the part behind it. Hence a certain part of the animal's weight must be exerted upon the shafts, in order to balance that of the carriage, which is thus thrown back, and which, as is evident from the figures, must be the same in both carriages, though the wheels of the one so much exceed those of the other in size, and the point T, where the wheel touches the plane, is much farther from the line of suspension in the large wheel than in the small one.

To remedy the inconvenience which must arise from placing the centre of gravity in the carriage low enough with respect to the wheels, it will be best to apply three or four wheels, placing them in such a manner that the line of gravity may always fall between the wheels, in whatever situation the carriage may probably be placed. Thus if the body A, fig. 78, be placed on four wheels, the axles of which are at B and C, it will be entirely supported between them, though more by C than B, even though the carriage

should be ascending an hill as steep as HI, viz. 50° degrees, which cannot ever happen in practice. Even in this case the animal would have no occasion to make exertions for preserving the balance of the carriage, though, had it been supported only by the axles of two wheels at S, far the greater part of the weight of the carriage would have been thrown behind, and the equilibrium could not have been preserved without the greatest difficulty. Hence it is plain, that the greater the distance betwixt the axles of three or four wheels applied to a carriage, the less liable will it be to have the line of gravity thrown out of its proper direction; but as this distance greatly augments the difficulty in turning a carriage, some medium is to be observed in this as well as other things.

What has been just now observed with regard to the preserving the balance of a carriage longitudinally, applies equally to the preventing it from being over-turned laterally upon uneven roads, or such as have one side much higher than the other. In order to this, we must take care to keep the line of gravity so far within the body of the carriage that it cannot be thrown out of it by any ordinary declivity of the road upon one side more than another. In the present case, however, as the wheels are not moveable on an axle in a lateral direction, we must consider the points of suspension to be those where the wheels touch the ground. Thus, let fig. 79. represent the cross section of a carriage moving upon two wheels; let C be its centre of gravity: it is plain, that in the position there represented, each of the points A and B sustains an equal share of the weight, and must do so as long as the carriage moves upon level ground: but if it be drawn along a road one side of which is higher than the other, such as is represented fig. 80. then the centre of gravity, and consequently the whole weight of the carriage, will bear upon the point of the wheel B, with this additional inconvenience, that the pressure does not lie perpendicularly but somewhat obliquely, by which the wheel is in great danger of being broken. To avoid inconveniences of this kind, the points of bearing upon the wheels are removed to a greater distance than the exact perpendicular, and this is called *diving* the wheels; the good effects of which are evident from the figure. The wheels are dished by inserting the spokes into the naves in such a manner that they may decline every way from the carriage. Some disadvantage, however, attends this contrivance, for the carriage thus takes up more room upon the road, which makes it more unmanageable; and when it moves upon plain ground, the spokes not only do not bear perpendicularly, by which means their strength is lessened, but the friction upon the nave and axle is made unequal, and the more so the more that the wheels are dished. To obviate these inconveniences, some have bent downwards the ends of the axles; but thus the good effects of the dish is entirely lost, for the wheels are thereby thrown erect, and the breadth of the dish doubly increased on the upper part of the carriage.

The practice of bending forward the ends of the axle is still worse; for thus the wheels are thrown out of that parallel direction which they should always preserve on the ground, and likewise increases the friction both on the shoulders of the axles, and like-

Wheel-carriages.

46
Of preventing a carriage from being over-turned.

Wheel-carriages.

wife on the ground; for the wheels, by rolling in this position, would soon come together if not prevented by the shoulders of the axles; whence in every revolution they must rub with considerable force upon the ground.

47
How the power of wheels may be augmented.

The power of wheels can only be augmented in two ways. 1. By increasing the length of that arm of the lever to which the power is applied; and, 2. By diminishing the friction betwixt the nave and axle. The former is only a temporary expedient in case of any obstacle which cannot be surmounted in the ordinary way. It is accomplished, by transferring the action of the animal's power from the centre to the upper part of the circumference of the wheel: thus the power of the lever will be nearly doubled, as is shown from fig. 71. for if the power be applied to the wheel at A, then the arm of the lever would be represented by the dotted line AO instead of CO; and the former being nearly twice as long as the latter, their powers must be in the same proportion. It is evident, however, that this mode of applying the animal's power can only be useful in any sudden emergency; for were we to attempt to reduce it into practice by winding a rope or chain about the circumference of the wheel, the animal must move twice as fast as the carriage. See this also exemplified in Plate CCLXXXV. fig. 58, where the moving power is represented by the weight P; the wheel EF turning between two toothed planes AB and CD. Here it is evident, that while one of the small divisions *ea*, *ac*, &c. moves forward its own length, the plane A must do the same, while the centre, by the motion of which only that of the wheel can be measured, moves but through half the space.

49
Of friction-wheels.

2. With respect to friction-wheels or rollers, the case is different; and we may apply these in as great numbers, and in as great a variety of ways as we please, without fear of inconvenience. The best method of applying them, according to Mr Anstice, is to have the wheels and axle fixed to one another, so that both may turn together. Two friction wheels a little overlapping each other, must then be fixed on each side of the body of the carriage, so that it may bear on the axle in the intersection of the wheels, as is represented in fig. 81. Here ABCD represents the body of the carriage, the large circle one of the wheels fixed to the axle E. The circumference of each of the friction-wheels F and G is supposed to be three feet, and that of their axles three inches. As the large wheel then revolves by the motion of the carriage, and thus transfers the friction from its circumference to its axle; so the friction of the axle itself is now transferred from the circumference of the friction-wheels to their axles. Every revolution of the great wheel, therefore, during which it passes over 18 feet of ground by means of the motion of the axle, puts the lesser wheels round one sixth part of their circle; and consequently their axles are moved through the same part of their circumference, the friction being thus reduced to that upon this small part; which being no more than half an inch, becomes 432 times less than it would have been on the large wheel without any motion on an axle, and 12 times less by means of the friction-wheels than without them. The axles on both sides indeed are in motion, but the calculation must be made as if only one moved; for the greater number of wheels

there are, the more will the friction be divided among them.

An objection of considerable weight arises to this method of fixing the wheels and axles together, that thus the wheels are prevented from moving with different velocities as they ought to do, when the carriage moves out of a right line; but this may be obviated by leaving the friction wheels loose upon their axles, by which means they will be at liberty to move with different velocities, at the same time that they will have the advantages of friction-wheels always as to one wheel of the carriage, and generally as to both.—The whole contrivance, however, seems likely to be entirely superseded by the following one of Mr Gamett of Bristol, who has obtained a patent for it. The general principle on which he proceeds is this. Between the axle and nave a hollow space is left to be filled up by solid equal rollers nearly touching each other. These are furnished with axles inserted into a circular ring at each end, by which their relative distances are preserved; and they are kept parallel by means of wires fastened to the rings between the rollers, and which are rivetted to them.

To understand the effect of this machinery we must consider, that if, when plane surfaces move with a roller between them, if the under one be fixed, the upper plane will put the rollers forward but with half the quantity of its own motion. This is owing to the reaction of the stationary plane, which causes the roller to move backward upon itself as much as the other causes it to move forward upon itself. Thus, let CD, fig. 82. be a fixed surface, and AB a moveable one, with a roller E between them; if B be moved forward to G, it will cause the roller to move to F, which is but half the distance that AB has moved; because it has rolled in a retrograde direction as far against the surface BA as it has gone forward upon the other. This is entirely owing to the resistance it meets with from CD; for if it did not touch that surface, but was attached by any other means to AB, it would be carried along with it through the whole space without any rolling motion. Hence it is clear, that if a roller be placed between the axle and nave of a wheel, and the latter be turned round, the roller will move with a retrograde motion upon the axle; and in order to carry it quite round, the nave must be turned as much beyond a whole revolution as is equal on its inner circumference to the whole circumference of the axle. To exemplify this, let ABCD, fig. 83. represent the nave of the wheel E, the inner circumference of which is 18 inches, and the axle so small that it may be considered as a point. Let F and G be two rollers closely fitted between them: if then the wheel be turned round, the rollers will also be carried along with it round the point which we consider as an axle; for there can neither be rolling nor friction against a mere point. But if the axle be of any sensible size, for instance one inch circumference, then must each roller move round by the motion of the nave against it, and the resistance of the angle on the opposite side. But in order to do this, it must roll in a retrograde direction upon the nave, and consequently the latter must go as far beyond a revolution as is equal to the circumference of the axle upon it, before the roller can go once round the axle, which in this case is by

Plate
CCLXXXVIII

Plate
CCLXXXV.

Wheel-carriages.

one 18th part of the circumference. Should the circumference of the axle be nine inches, and that of the inner part of the nave remain as before, the wheel must perform one revolution and an half before the roller could be moved once round, and so on in the same proportion : but as the circumference of an axle must always be less than the inner part of a nave turning upon it with rollers between them, it never can amount to two revolutions of the wheel round the axle, however nearly it may approach to it ; for no segment of a circle can ever be a straight line.

It will now be apparent, that if several rollers be placed all round between the nave and axle, whichever way the wheel be turned there cannot be any real friction, but merely a rolling of the rollers. If likewise these rollers be all of one size, and very nicely fitted to the cavity, they will keep their places without shifting, and very effectually answer the purpose of destroying friction. As such rollers, however, were very liable to be displaced by accident, the use of them was neglected, till Mr Gamett suggested the improvement already mentioned, and which is represented in fig. 84. Here ABCD represents a piece of metal to be inserted into the nave of a wheel, of which E is the axle, and 1, 1, 1, &c. rollers of metal having axes inserted into the brazen circle which passes thro' their centres ; and both circles being rivetted together by means of bolts passing between the rollers from one side of the nave to the other ; and thus they are always kept separate and parallel. By this method, indeed, some friction unavoidably takes place betwixt the axles of the rollers and their sockets in the brass-rings ; but as the quantity of friction depends principally on the force by which the rubbing surfaces are pressed upon each other, and as in this case there is but the slight pressure occasioned by those accidental circumstances which would bring the rollers together, the friction must be too trifling to be noticed.

Thus far with regard to wheel-carriages in general. We must now make some remarks on the methods of drawing them, and the construction of particular carriages.—Men, by reason of their upright form, are by no means fitted for horizontal draughts ; but animals who go upon all fours are remarkably so. In Britain horses are commonly made use of ; but mules, oxen, sheep, and dogs, in other parts of the world. In all animals, however, the capacity for drawing a load depends upon their weight as well as their absolute strength. Thus it may happen, that a very heavy horse will draw a load, which a lighter though stronger one could not move ; and this will always happen, when the weaker horse exceeds the other in weight more than he is exceeded by him in strength. It is well known that the weight, as far as it goes, reacts upon the horse, and pulls him back as much as he pulls it forward, until the exertions of the muscles of the animal resisted, by the solid ground, overcome the resistance of the load upon the moveable wheels, and it goes forward in proportion to the excess of the one power over the other. If the horse were put upon a moveable plane, and attempted to draw a load upon the solid ground, instead of pulling it forward he would pull himself back. The horse has two sources of power in drawing a load, viz. his strength and

weight. The former is the source of velocity ; and as we find the actual power of any inanimate body in motion by multiplying the velocity into its quantity of matter, so do we find the power of a horse to draw a load, by considering his weight as well as absolute strength. There are even many instances in common practice, where it is useful to increase the weight of an horse or other animal ; and therefore when horses are employed to draw mills, it is usual to put a small load upon their backs in order to increase their absolute momentum. Where the animals are equal in strength and momentum, however, the only difference that can take place in the weights they draw must arise from the convenience or inconvenience of the carriages to which they are yoked, or of the roads upon which they walk. A load breast-high is much more easily drawn than one which is dragged along the ground, because the power of the animal is then exerted directly against it ; and this holds good whether the horses go up or down hill. In descending, indeed, as the load is then higher with regard to the horse than when it is on a plane, he will consequently pull it with the greater force ; but in this case, its own gravity conspires with the draught, and will likewise help the load to descend ; so that in this case the animal has an opportunity of exerting his greatest power when there is the least necessity, nay, when it is often inconvenient.

In all carriages with four wheels the two fore ones are made of a much smaller size than the hind ones, both for the sake of turning more easily, and likewise that there may be no danger of cutting the braces ; but were both the fore and hind wheels to be of the same height, the carriage would be drawn with much greater ease. It is imagined indeed by the drivers of carriages, that the high hind wheels push on the fore-wheels ; but this is evidently absurd ; for the fore-wheels must turn as many times round oftener than the large ones as the latter exceed them in size. Thus, if we suppose the circumference of the large wheels to be 18 feet, and that of the small ones only six, it is evident that the latter must turn round three times for once that the large ones turn round. Supposing the carriage therefore to be loaded equally on both axles, it is plain that by the greater friction upon the fore-axle than the other, it must wear out much sooner, and that as much as the fore-wheels are smaller than the hind ones. But it is the universal practice of those conversant in loading and driving carriages, to put a much greater load upon the fore than the back axle. Thus the friction not only becomes greatest where it ought to be least, but the small wheels must necessarily sink deeper into the ground than the large ones, which they are at any rate inclined to do from their size. The only danger in laying the greatest load upon the hind axle is, when the carriage goes up a very steep ascent ; but in the few cases in which this may happen, a small temporary weight laid upon the pole betwixt the horses would prevent all danger of overfetting.

To confirm these reasonings by experiment, let a small model of a waggon be made, with its fore-wheels $2\frac{1}{2}$ inches in diameter, and its hind-wheels 4 ; the whole model weighing about 20 ounces. Let this little carriage be loaded any how with weights, and have a

Wheel-carriages.

Wheel-carriages.

small cord tied to each of its ends, equally high from the ground it rests upon; and let it be drawn along a horizontal board, first by a weight in a scale hung to the cord at the fore-part; the cord going over a pulley at the end of the board to facilitate the draught, and the weight just sufficient to draw it along. Then turn the carriage, and hang the scale and weight to the hind-cord, and it will be found to move along with the same velocity as at first: which shows that the power required to draw the carriage is all the same, whether the great or small wheels are foremost; and therefore the great wheels do not help in the least to push on the small wheels in the road.

Hang the scale to the fore-cord, and place the fore-wheels (which are the small ones) in two holes, cut three eighth parts of an inch deep in the board; then put a weight of 32 ounces into the carriage over the fore-axle, and an equal weight over the hind-one: this done, put 44 ounces into the scale, which will be just sufficient to draw out the fore-wheels: but if this weight be taken out of the scale, and one of 16 ounces put into its place, if the hind-wheels are placed in the holes, the 16 ounce weight will draw them out; which is little more than a third part of what was necessary to draw out the fore-wheels. This shows, that the larger the wheels are, the less power will draw the carriage, especially on rough ground.

Put 64 ounces over the axle of the hind-wheels, and 32 over the axle of the fore-ones, in the carriage; and place the fore-wheels in the holes: then put 38 ounces into the scale, which will just draw out the fore-wheels; and when the hind-ones come to the hole, they will find but very little resistance, because they sink but a little way into it.

But shift the weights in the carriage, by putting the 32 ounces upon the hind-axle, and the 64 ounces upon the fore-one; and place the fore-wheels in the holes: then, if 76 ounces be put into the scale, it will be found no more than sufficient to draw out these wheels; which is double the power required to draw them out when the lighter part of the load was put upon them; which is a plain demonstration of the absurdity of putting the heaviest part of the load in the fore-part of the waggon.

Every one knows what an outcry was made by the generality, if not the whole body, of the carriers, against the broad-wheel act; and how hard it was to persuade them to comply with it, even though the government allowed them to draw with more horses, and carry greater loads than usual. Their principal objection was, that as a broad wheel must touch the ground in a great many more points than a narrow wheel, the friction must of course be just so much the greater; and consequently there must be so many more horses than usual to draw the waggon. It is believed that the majority of people were of the same opinion; not considering, that if the whole weight of the waggon and load in it bears upon a great many points, each sustains a proportionably less degree of weight and friction, than when it bears only upon a few points: so that what is wanting in one is made up in the other; and therefore will be just equal under equal degrees of weight, as may be shown by the following plain and easy experiment.

Let one end of a piece of pack-thread be fastened

to a brick, and the other end to a common scale for holding weights: then, having laid the brick edgewise on a table, and let the scale hang under the edge of the table, put as much weight into the scale as will just draw the brick along the table. Then taking back the brick to its former place, lay it flat on the table, and leave it to be acted upon by the same weight in the scale as before, which will draw it along with the same ease as when it lay upon its edge. In the former case, the brick may be considered as a narrow wheel on the ground; and in the latter, as a broad wheel. And since the brick is drawn along with equal ease, whether its broad side or narrow edge touches the table, it shows that a broad wheel might be drawn along the ground with the same ease as a narrow one (supposing them equally heavy), even though they should drag, and not roll, as they go along.

As narrow wheels are constantly sinking into the road, they not only prove very destructive to the highways over which the carriages move, but by reason of this very sinking, they must be accounted as going continually up hill in some degree, even when drawn upon plain ground. These inconveniences are obviated by the use of broad wheels; and indeed the utility of these is so obvious, that it seems surprising how the use of narrow wheels is on any occasion permitted by the legislature. The wheels ordinarily used for waggons are nine inches broad; but of late a practice has been introduced of using rollers 16 inches broad; by which the inconveniences of the narrow wheels are removed, and the greatest weights may be drawn over the very worst roads, not only without making them worse, but greatly to their improvement. It has been objected, that broad wheels soon accumulate in clayey roads so much matter that it would soon equal an ordinary load; but, not to mention that such roads ought to have no existence in a country where such sums are annually paid for their reparation, it is evident, that passing heavy rollers over them is the only method to give that firmness to clay which is necessary for its supporting the animals who walk over it; and indeed many of the roads in this country, by reason of the continual poaching by wheels and feet of horses, &c. become throughout a great part of the year almost impassable by people on foot. The legislature appear to be very sensible of the advantages derived from these rollers, and accordingly allow such carriages as are furnished with them to go toll-free.

In the transactions of the Royal Irish Academy for 1788, we meet with some curious observations on the subject of wheel-carriages, by Mr Lovell Edgeworth. This gentleman informs us, that he was present in London in 1773, at a set of experiments tried in order to determine the comparative advantages of low and high wheels. The apparatus for these experiments was constructed with the greatest accuracy. The carriages themselves were made by the best workmen in London, and they were drawn along a smooth table by silk strings of small diameters put over a pulley nicely constructed, and fitted up in such a manner as to have scarce any friction. On applying a weight to the end of the string which passed over the pulley, little difference appeared in the velocities with which the carriages passed along the table, whether the wheels were high or low; but what appeared surprising was, that when obstacles were put

Wheel-carriages.

in their way, sometimes the high and sometimes the low wheels had the advantage, according to the different shapes and sizes of the obstacles. "It appears at first view (says Mr Lovell), that the force which drew these carriages was employed only in overcoming the friction of the axle-tree, or in lifting the weight over the obstacle. But I suspected at the time, and have since been convinced, that an obstruction of another sort existed more considerable than either of these which I have mentioned, and which has not to my knowledge been taken notice of by any writer upon mechanics."

52
Supposed to be independent of gravity.

This obstruction is no other than the *vis inertia* of matter, which has so much engaged the attention of philosophers, and the non-entity of which, in distinction from the power of gravity, seems now to be pretty generally admitted. The argument used for its existence by Mr Edgeworth is as follows: "After a carriage has been once set in motion upon a smooth road with any given velocity, its motion, so long as that velocity is continued, is neither retarded nor promoted by the *vis inertia*; but whenever it passes over any height, not only the weight of the carriage must be lifted up, but the *vis inertia* of that weight must be overcome in a new direction; and as much velocity must be communicated to it in that new direction as will enable it to rise to the height of the obstacle while it passes over its base. When an obstacle is of such a size and shape that a wheel of six feet diameter must strike the top of it at once, and not roll from the bottom upwards, and when its shape will permit a smaller wheel to touch it during its whole ascent, as there is more time allowed for overcoming the *vis inertia* of its weight in the latter case than in the former, the smaller wheel may be drawn forward by a less power than the larger, notwithstanding the advantage of a lever, which is in favour of the larger wheel."

To determine this, our author made use of an inclined plane five or six feet long and one foot high, placed on a smooth horizontal floor. He then assumed the distance to which the carriage was driven on the floor by the velocity acquired in descending the plane, as a measure of the force with which it could overcome any obstacle placed in its way; and consequently the diminution of the distance was the measure of the resistance itself. Not satisfied with this apparatus, however, he screwed a circle of iron three feet three inches in diameter upon a solid floor. In the centre of this circle he erected an upright axis or roller upon two pivots, one resting in a socket of brass upon the floor, the other in a bridge raised across the machine. Around the axis was wound a small silk cord, with a scale and weights fastened to it, which passed over a pulley into an adjoining stair-case, and turned the axis with a determined velocity. An horizontal arm of wood extended from the axis to the circumference of the inner circle, and to the extremity of the arm was fastened a piece of steel in form of the axle-tree of a carriage, having a wheel upon it, which by the motion of the axis was carried round upon its edge like the stone of a tanner's mill. The arm was furnished with an hinge, by means of which the wheel could rise up and pass over any obstacle which stood in its way. Above this was another arm, having on its extremity

a tin vane, which by its resistance to the air regulated the motion of the machine. On putting weights into the scale, it was found that eight or ten turns were necessary to give the wheel an uniform velocity, which was preserved in all the experiments, any resistance thrown in the way being overcome by an addition of weight, and consequently this addition being always an accurate measure of the resistance.

On loading the wheel so as to weigh about four pounds, it acquired a velocity of ten feet in a second by nearly five pounds and an half; but on placing in its way an obstacle only a quarter of an inch high, six pounds and an half were required to cause the wheel pass over it. Two such obstacles required fourteen and an half pounds; but on substituting two obstacles of the same height, but making an inclined plane three quarters of an inch long, it required only two pounds to overcome their resistance. "The difference therefore (says he) between two and fourteen, must be attributed to the *vis inertia*; for the velocities of the carriage and the heights of the obstacles remaining the same, the only difference that exists is, that in the one case the wheel has much more time to surmount the obstacle, than in the other, and consequently had much less *vis inertia*."

On this piece of reasoning, however, it is impossible to avoid making the following remark, *viz.* that nothing happens but what ought to do so upon the common principles of mechanics. One obstacle, when upright, required six pounds and an half to overcome it; but when an inclined plane three times the length was added to it, it ought then to have been overcome by a third part of the power, that is, by something more than two pounds; and the reason why something less than the third part was required, seems to have been the advantage the wheel had by acting as a lever; as has been already observed on the principles of Mr Amont. There is not therefore the least occasion to apply to a *vis inertia*, or any obscure principle, for a solution of what may so easily be solved upon the common principles of mechanics and gravity.

Mr Edgeworth concludes his observations with some remarks on the use of springs, which are found greatly to facilitate the draught of carriages. "Whatever (says he) permits the load to rise gradually over an obstacle without obstructing the velocity of the carriage, will tend to facilitate its draught; and the application of springs has this effect to a very considerable degree: the same weight of four pounds being drawn over the same obstacles, when springs were put between the load and the carriage, by four pounds instead of 14. This remarkable difference points out the great advantage of springs in rough roads; an advantage which might be obtained for heavy waggons, as well as for other carriages, by a judicious application of the same means.

53
Use of springs in carriages.

"It appears from the Memoirs of the French academy, that the idea of applying springs to carriages had occurred to M. Thomas in the year 1703; who has given a drawing of a carriage constructed upon this principle many years before it was attempted to be put in execution. So little expectation had he of success, that he expressly mentions it as a theory which could not be reduced to practice: he had, however, no notion of applying springs to facilitate the draught,

but

Wheel-carriages.

but merely for the convenience of the rider; and I apprehend that it is not at present commonly imagined that springs are advantageous for this purpose; nor would it at first sight appear credible, that, upon a rough paved road, such as are common in Cheshire and other parts of England, a pair of horses could draw a carriage mounted upon springs with greater ease and expedition than four could draw the same carriage if the springs and braces were removed, and the carriage bolted fast down to the perch."

54 On high and low carriages.

Mr Lovell made also some experiments with high and low, long and short, carriages, in order to determine which was the most advantageous, but could not recollect the particular results of each experiment. He was, however, assured, that the preference lately given in England to high carriages is ill-founded; and that, though in smooth roads, the height of the carriage is a matter of indifference, yet in rough roads it is very disadvantageous. The length of carriages also, if their weight be not increased, is a matter of indifference, except in very uneven roads, and where there are deep ruts; long carriages being preferable in the former case, and short ones in the latter.

The reason why springs so much facilitate the draught of carriages seems to be, not only that they allow the wheels to pass more gradually over the obstacles, as Mr Edgeworth says, but that by their elasticity they make the carriage bound upwards every moment for a small way. Thus its gravity is for that moment in a great measure counteracted, and the progressive motion which it has already acquired is at liberty to act more freely in pushing it forward; for were it possible very suddenly to take away the horses from a carriage mounted on springs, and moving with considerable velocity, it would continue for some time to move of itself; the weight in this case acting as a fly upon any mechanical engine, by means of which the machine accumulates a certain quantity of power, and will keep itself in motion for a considerable time after the hand is taken away from it. The weight of all carriages indeed has some effect of this kind, otherwise the draught would require an intolerable exertion of strength; and it is to be observed, that this tendency to proceed in the direction in which it is once set a-going, is remarkable in all great quantities of matter, and very perceptible even when weights are pulled directly upward; for in raising great weights by a crane, the burden is lifted with considerably more ease when near the top than at bottom, even after making every necessary allowance for the weight of the rope, &c.

55 A carriage to go without horses, or any other force than what it receives from the passengers. Fig. 85.

By means of wheels, some people have contrived carriages to go without horses, or any other moving power than what was given by the passengers, by the wind, &c. One of these is represented by ABCD. It is moved by the footman behind it; and the forewheels, which act as a rudder, are guided by the person who sits in the carriage (A).

Between the hind-wheels is placed a box, in which is concealed the machinery that moves the carriage. AA (fig. 86.) is a small axis fixed into the box. B is a pulley, over which runs a rope, whose two ends are

fastened to the ends of the two levers or treddles CD, whose other ends are fixed in such manner in the piece E, which is joined to the box, that they can easily move up and down. F, F, are two flat pieces of iron that are joined to the treddles, and take the teeth of the two wheels H, H, which are fixed on the same axis with the hind-wheels of the carriage, I, I.

Wheel-carriages.

It is evident, that when the footman behind presses down one of the treddles, suppose C, with his foot, he must bring down one of the pieces of iron F, and consequently turn the wheel H that is next to it; and at the same time, by means of the rope that goes over the pulley, he must raise the other treddle D, together with its piece F, which being thrust down will turn the other wheel H; and so alternately: and as the great wheels are fixed on the same axis, they must necessarily move at the same time.

It is easy to conceive, that if the ends of the treddles next E, instead of being placed behind the carriage, were turned the opposite way, so as to come under the feet of the person who sits in it, he might move it with equal, or even greater facility, than the footman, as it would then be charged with the weight of one person only.

A machine of this kind will afford a salutary recreation in a garden or park, or on any plain ground; but in a rough or deep road must be attended with more pain than pleasure.

Another contrivance for being carried without To fail as draught, is by means of a sailing chariot or boat fixed fast, with a fair wind, on four wheels, as AB; which is driven before the fair wind, by the sails CD, and guided by the rudder E, by land, as by water. In a chariot of this kind, the wheels should be farther Fig. 87. afunder, and the axle-trees longer, than in other carriages, to prevent overturning.

A machine of this sort was constructed in the last century by Stephanus, at Scheveling in Holland, and is celebrated by many writers. Its velocity with a strong wind is said to be so great, that it would carry eight or ten persons from Scheveling to Putten, which is 42 English miles distant, in two hours.

Carriages of this kind are said to be frequent in China; and in any wide, level country, must be sometimes both pleasant and profitable. The great inconvenience attending this machine is, that it can only go in the direction the wind blows, and even not then unless it blow strong: so that, after you have got some way on your journey, if the wind should fail, or change, you must either proceed on foot or go back. Some remedy for this inconvenience will be found in the next contrivance. The Hollanders have, or had, small vessels, something of this kind, that carry one or two persons on the ice, having a sledge at bottom instead of wheels: and being made in the form of a boat, if the ice break the passengers are secured from drowning.

To fail against the wind: Let ABCD be the body of a failing chariot: M the mast, to which are fixed the wings or sails EFGH; the two frith of which, EF, the wind are here supposed to be expanded by the wind; R is the rudder by which it is guided. Therefore the wind driving To fail by land against the wind. Fig. 88.

(A) This machine was invented by M. Richard, a physician of Rochelle, and was exhibited at Paris in the last century. It is described by M. Ozanam in his *Recreations Mathematiques*.

driving the sails round, with the mast M, and the cog-wheel K, take the teeth placed perpendicular to the sides of the two fore-wheels of the carriage, and consequently keep it in continual motion.

The body of this machine should not be large, nor placed very high, not only to prevent overturning, but that its motion may not be thereby impeded; for the velocity will be in proportion to the force of the wind on the sails to that on the body of the machine. Therefore, if they be both equal, it will stand still; or if the force on the body be greatest, it will go backwards; unless there be a contrivance to lock the wheels. The upper part of the machine next A, may be made to take off when the wind is contrary; and there may be another set of sails placed between the two hind-wheels, which will considerably increase its velocity. But after all, for general use, a common carriage must be preferable: for this cannot be expected to go up a moderate ascent without great difficulty; nor down a declivity, when there is a strong wind, without danger; and even on level ground, if the road be in any degree rough, its progress must be very slow, attended both with difficulty and danger. In an open country, however, where there is a large tract of level and smooth ground, and frequent strong winds, a machine of this sort will certainly be very convenient; and in most countries, when made of a small size, may be useful to young people, by affording them a pleasant and healthful exercise.

The un-
invertible car-
riage.
fig. 89.

A carriage, the body of which is incapable of being overturned, may be made as follows. The body must consist of a regular hollow globe, as AB, at the bottom of which is to be an immovable weight, and which must be proportioned to the number of persons or the load the machine is intended to carry. Round the globe must go two horizontal iron circles D, E, and two others F, G, that are perpendicular to the former. All these circles must be made exactly to fit the globe, that it may move freely in every direction. The two horizontal circles are to be joined on each side by a perpendicular bar, one of which is expressed in the figure by HI. All these irons should be lined with leather, to prevent unnecessary friction. The body of the carriage may be either of leather or hard wood; but the latter will be most eligible, as least liable to wear. The wheel on each side is to be fastened to the perpendicular bar by means of a handle K that keeps it steady.

Now the body of this machine moving freely in the iron circles every way, the centre of gravity will always lie at C; therefore, in whatever position the wheels are, or even if they overturn, the body of the carriage will constantly remain in the same perpendicular direction.

At L is placed a pin, round which is a hollow moveable cylinder: this pin moves up and down in the groove MN, that it may not impede the perpendicular motion of the circles, at the same time that it prevents the body of the machine from turning round in a horizontal direction. O is one of the windows, P the door, and QR the shafts to this machine.

When a carriage of this sort is intended for a single person, or a light weight, it may be hung on swivels, in the same manner as the rolling lamp or the sea-com-

pafs, which will make its horizontal motion still more regular: and when it is designed to carry several persons, by adding another perpendicular bar on each side, between the two horizontal circles, it may be placed on four wheels. The body of this machine should be frequently oiled or greased, not only to prevent any disagreeable noise that may arise from its rubbing against the circles, but to prevent unnecessary wear in the several parts.

This carriage is not intended for smooth roads, or a regular pavement; there certainly, those of the common construction are much preferable; nor should a carriage totally free from irregular motion be sought after by those who are in perfect health: but there are many persons, subject to different disorders, who by being obliged to travel over rough roads in the common carriages, suffer tortures of which the healthful have no idea; to all these, therefore, and to every one who is forced to travel through dangerous roads, a carriage of this sort must doubtless be highly desirable.

As this design may appear to some persons, on a superficial view, impracticable, we shall here insert an account of a similar carriage, which we have taken from the first volume of the *Abridgement of the Philosophical Transactions*, by Lowthorp. There is not, however, any description of the manner in which that machine was constructed. The account is as follows: "A new sort of calash described by Sir R. B. This calash goes on two wheels; carries one person; is light enough. Though it hangs not on braces, yet it is easier than the common coach. A common coach will overturn if one wheel go on a superficies a foot and a half higher than the other; but this will admit of the difference of three feet and one-third in height of the superficies, without danger of overturning. We chose all the irregular banks, and sides of ditches, to run over; and I have this day seen it, at five several times, turn over and over, and the horse not at all disordered. If the horse should be in the least unruly, with the help of one pin you disengage him from the calash without any inconvenience (*a contrivance of this sort may be easily added to the foregoing design*). I myself have been once overturned, and knew it not till I looked up and saw the wheel flat over my head: and if a man went with his eyes shut, he would imagine himself in the most smooth way, though at the same time there be three feet difference in the height of the ground of each wheel."

SECT. V. Of Mills.

MILL, in the proper sense of the word, signifies a machine for grinding corn, though, in a more general sense, it is applied to all machines which have an horizontal circulatory motion. Mills are distinguished by particular names, sometimes taken from the powers by which they are moved, and sometimes from the uses to which they are applied. Hence they are called hand-mills, horse-mills, water-mills, fulling-mills, wind-mills, corn-mills, levigating mills, boring-mills, &c.

The most simple of these is the *hand mill*, represented fig. 90, where A and B represent the two stones between which the corn is ground, and of which the upper one A turns round, but the lower one (B) remains

59
A hand-
mill.

Mills.

mains fixed and immovable. The upper stone is five inches thick, and 21 inches broad; the lower one somewhat broader. C is a cog-wheel, having 16 or 18 cogs, which go into the trundle F, having nine spokes fixed to the axis G, the latter being firmly inserted into the upper stone A, by means of a piece of iron. H is the hopper into which the corn is put; I the shoe to carry it by little and little through a hole at K, in betwixt the stones, where being ground into meal, it comes out through the eye at L. Both stones are inclosed in a circular wooden case, of such a size as will admit the upper one to run freely within it.—The under surface of the upper stone is cut into grooves, as represented at Q, which enable it to throw the meal out at the eye L more perfectly than could be done if it was quite plain. Neither of them are entirely flat, the upper one being somewhat concave, and the under one convex. They nearly touch at the edges, but are at some distance in the middle, in order to let the corn go in between them. The under stone is supported by strong beams, not represented in the figure; the spindle G stands on the beam MN, which lies upon the bearer O. One end of this bearer rests upon a fixed beam, and the other has a string fixed to it, and going round the pin P, by the turning of which the timbers O and MN may be raised or lowered, and thus the stones put nearer, or removed farther from each other, in order to grind fine or coarse. When the corn is to be ground, it must be put into the hopper by little at a time. A man turns the handle D, and thus the cog-wheel and trundle are carried round also together with the stone A. The axis G is angular at K; and, as it goes round, shakes the shoe I, and makes the corn fall gradually through the hole K. The upper stone going round grinds it, throwing out the meal, as already said, at the eye L. Another handle, if thought proper, may be put at the other end of the handle E. The spindle must go through both stones, in order to reach the beam MN, and the hole through which it passes is fastened with leather or wood, so that no meal can pass through. Mr Emerfon, from whom this account is taken, observes, that “it is a pity some such mills are not made at a cheap rate, for the sake of the poor, who are much distressed by the roguery of the millers.”

60
Horse-mill.

The construction of a horse-mill differs not from that of the hand-mill just described, excepting that instead of the handle D, the spindle is furnished with a long horizontal lever and cogged wheel, which turns the trundle and stones, as already mentioned.—The stones are much heavier than in the hand-mill.

61
Water-mills.

The mills most commonly in use for grinding corn are water-mills, the construction of which is not essentially different from that of the hand or horse-mills.—The lower mill-stone, as already mentioned, is fixed, but the upper one moveable upon a spindle. The opposite surfaces of the two stones are not flat, but the one convex and the other concave, though in a very small degree. The upper stone, which is six feet in diameter, is hollowed only about an inch in the middle, and the other rises three quarters of an inch. They approach much nearer each other at the circumference, and the corn begins to be ground about two thirds of the radius distant from the circumference, and there it makes the greatest resistance, the space between the

N° 199.

two stones being in that place only about two-thirds or three-fourths of the thickness of a grain of corn; but as these stones, as well as those of the hand-mill or horse-mill, can be separated a little from each other, the meal may be made fine or coarse in them, as well as in the two former mills.

In order to cut and grind the corn, both the upper and under stones have furrows cut in them, as is observed in the hand-mill. These are cut perpendicularly on one side, and obliquely upon the other, by which means each furrow has a sharp edge, and by the turning of the stones, the furrows meet like a pair of scissars, and by cutting the corn, make it grind the more easily. They are cut the same way in both stones when they lie upon their backs, by which means they run crosswise to each other when the upper one is inverted and turned round; and this greatly promotes the grinding of the corn, great part of which would be driven onward in the lower furrows, without being ground at all, if both lay the same way.—When the furrow becomes blunt and shallow by wearing, the running stone must be taken off, and the furrows cut deeper in both by means of a chissel and hammer. Thus, however, by having the furrows cut down a great number of times, the thicknesses of both stones are greatly diminished; and it is observed, that in proportion to the diminution of the thickness of the upper stone, the quantity of flour also diminishes.

By means of the circular motion of the upper stone, the corn is brought out of the hopper by jerks, and recedes from the centre towards the circumference by the centrifugal force; and being entirely reduced to flour at the edges when the stones nearly touch one another, it is thrown at last out at the hole called the eye, as already mentioned. In Scotland, it is frequent to have the stones without any furrows, and only irregularly indented with small holes, by means of an iron instrument. Stones of this kind last a much shorter time than those with furrows, the latter being fit for use for 30 or 40 years, while the former seldom or never last more than seven. The under mill-stone is considerably thicker than the upper; and therefore, when both have been considerably worn by use, the lower one is frequently taken up, and the upper one put in its place, the former being converted into a running-stone.

Fig. 91 shows the construction of a common water-mill, where AA is the large water-wheel, commonly about 17 or 18 feet diameter from a, the extremity of any float-board, to b the extremity of the opposite one. This wheel is turned round by the falling of the water upon the boards from a certain height, and the greater the height, provided the water runs in an uninterrupted stream, the smaller quantity will be sufficient to turn the mill. This wheel is without the mill-house, but the wheel has an axle BB of considerable length, which passes through a circular hole in the wall, and has upon it a wheel D, of eight or nine feet diameter, having 61 cogs, which turn a trundle E of ten flaves or spokes; by which means the trundle, and consequently the mill-stone, will make six revolutions, and one-tenth for every revolution of the wheel. The odd cog, commonly called the *hunting cog*, is added, that as every one comes to the trundle it may take the staff behind that one which it took at the last revolution;

Mills.

62

Of water-mills.
Plate
CXXVIII.

Mills. tion; and thus all the parts of the cogs and rounds which work upon one another will wear equally, and to equal distances from another, in a little time; by which means a true uniform motion will be produced through the whole work. The trundle is fixed upon an iron axis called the spindle, the lower end of which turns in a brass pot fixed at F in the horizontal beam ST, called the *bridge-tree*; and the upper part of the spindle turns in a wooden bush, fixed into the lower mill-stone, which lies upon beams in the floor YY. The top part of the spindle above the bush is square, and goes into a square hole in a strong iron cross *abcd*, fig. 92, called the *rynd*; under which, and close to the bush, is a round piece of thick leather upon the spindle, which it turns round at the same time that it does the rynd. The latter enters into the grooves in the under surface of the running mill-stone G, fig. 91, and thus turns it wheel along with the trundle E, by means of the cog-wheel D. In the middle of the upper mill-stone is a large hole called the *eye*, through which the middle part of the rynd and upper part of the spindle may be seen; the ends being hid in the grooves below the stone. The end T of the bridge-tree TS, which supports the upper mill-stone G upon the spindle, is fixed into a hole in the wall; and the end S is let into the beam QR called the *brayer*; one end R of which remains fixed in a mortise, while the other end Q hangs by a strong iron rod P, which goes through the floor YY, and has a screw-nut on its top O; by the turning of which nut the end Q of the brayer is raised or depressed at pleasure, along with the bridge-tree TS and upper mill-stone. Thus the upper mill-stone may be raised as high from the under one, or let down as close to it, as the miller pleases; by which means the meal or flour is made either coarse or fine at pleasure. The upper mill-stone G is inclosed in a round box H, which leaves a vacant space of about an inch all round. On the top of this box stands a frame for holding the hopper *kl*, at which hangs the shoe l, by two lines fastened to the hinder part of it, fixed upon hooks in the hopper, and by one end of the string K to the fore part of it at i, the other end being twisted round the pin L. As the pin is turned one way, the string draws up the shoe closer to the hopper, and so lessens the aperture between them; and as the pin is turned the other way, it lets down the shoe, and widens the aperture. If it be drawn quite up to the hopper, no corn can fall out from the latter into the mill, and the quantity will be greater or less as the shoe is farther from the hopper or nearer to it. This happens by reason of the hopper being open at bottom, and the shoe at the forepart towards the end i over the middle of the eye of the mill-stone. There is also a square hole in the top of the spindle, in which is put the feeder *e*, fig. 92. Thus the shoe is jogged three times in each revolution, and the corn runs constantly down from the hopper through the shoe into the eye of the mill-stone, where it falls upon the top of the rynd, and, by the motion of that and of the leather beneath, is introduced betwixt the stones, and by the violent motion of the upper one acquires a centrifugal force; and proceeding gradually from the eye of the mill-stone towards the circumference, is thrown at last out in flour, at the hole called the eye of the mill.

VOL. X. Part II.

Some degree of nicety is requisite in feeding the mill; for if too great a quantity be poured into it, the stones are separated from each other more than they ought to be, and their motion is also impeded; while, on the other hand, if it be fed too slowly, the stone moves with too great velocity, and the attrition of the two is apt to make them strike fire. This matter is regulated by turning the pin L backwards or forwards as the miller thinks proper.

Sometimes, where plenty of water can be had, there are two trundles applied to the cog-wheel by means of a single large one turned immediately by the perpendicular cog-wheel, and carrying round with it an horizontal cogged wheel; on each side of which are placed the smaller trundles above-mentioned carrying the stones. In like manner, the water-wheel may be made to drive fanners, boulding-mills, &c. but it must always be remembered, that by complicating machinery to a great degree, it becomes more ready to give way; and the frequent reparation of which it stands in need, will, by the delay of business, be found at last more expensive than if separate machines had been used.

The wind-mill is furnished with an apparatus similar to the water-mill, but necessarily differs in the external apparatus for applying the power. This is done by means of the two arms AB and CD, fig. 93, intersecting each other at right angles in E, and passing through the axis EF, and about 32 feet in length.—On these yards are placed two sails or vane, in the shape sometimes of parallelograms, and sometimes of trapeziums, with parallel bales; the greater whereof HI is about six feet, and the length of the smaller FG is determined by radii drawn from the centre E to I and H.

As the direction of the wind is very uncertain, it becomes necessary to have some contrivance for turning the sails towards it, in order to receive its force in whatever way it may turn; and for this purpose two general methods are in use. In the one, the whole machine is sustained upon a moveable arbor or axis, perpendicular to the horizon, and which is supported by a strong stand or foot very firmly fixed in the earth; and thus by means of a lever the whole machine may be turned round as occasion requires. In the other method, only the roof, which is circular, can be turned round by means of a lever and rollers, upon which the circular roof moves. This last kind of wind-mill is always built of stone, in the form of a round turret, having a large wooden ring on the top of it, above which the roof, which must likewise be of wood, moves upon rollers, as has been already mentioned. To effect this motion the more easily, the wooden ring which lies on the top of the building is furnished with a groove, at the bottom of which are placed a number of brass truckles at certain distances, and within the groove is placed another ring, by which the whole roof is supported. The beams *ab* and *ac* are connected with the moveable ring, and a rope is fastened to the beam *ab* in *b*, which at the other extremity is fitted to a windlass or axis in peritrochio; and this rope being drawn through the iron hook G, and the windlafs turned round, the sails and roof will be turned round also, in order to catch the wind in any direction. Both these methods of construction have their advantages and disadvantages. The former is the least expensive, as the whole may be made of

5 D

wood,

Mills.

wood, and of any form that is thought proper; while the other requires a costly building of stone: and the roof being round, the building must also be so, while the other can be made of any form, but has the inconvenience of being liable to be carried off altogether by a very high wind, of which an instance occurred not long ago in Essex.

Fig. 94. shows the internal mechanism of a wind-mill. AHO is the upper room; H o Z the lower one; AB the axle-tree passing through the mill; STVW the sails covered with canvas set obliquely to the wind, and turning round in the order of the letters. CD is the cog-wheel, having about 48 cogs *aaa*, &c. which carry round the lantern EF, having eight or nine trundles *ccc*, &c. along with the axis GN. IK is the upper mill-stone, LM the lower one; QR is the bridge supporting the axis or spindle GN, which rests upon the beams *cd*, XY, wedged up at *c*, *d*, and X: ZY is the lifting tree, which stands upright; *ab* and *ef* are levers, having Z and *e* as centres of motion; *fgbi* is a cord, with a stone *i* wound about the pins *g* and *b*, and which thus serves as a balance or counterpoise. The spindle *t* N is fixed to the upper mill-stone IK by means of a piece of iron called the rynd, and fixed in the lower side of the stone, the whole weight of which rests upon a hard stone fixed in the bridge QR at N. The trundle EF and axis G may be taken away; for it rests its lower part by *t* in a square socket, and the top runs in the edge of the beam *w*. By bearing down the end of the lever *fe* we raise *b*, which raises also ZY, and this raises YX, which lifts up the bridge QR, with the axis NG, and the upper stone IK; so that by this contrivance the stones may, as in a water-mill, be set at any distance. The lower stone is fixed upon strong beams, and is broader than the upper one; the flour being conveyed through the tunnel *no* into a chest. P is the hopper into which the corn is put, and which runs along the spout *r* into the hole *s*, and so falls between the stones, where it is ground. The square axis G *t* shakes the spout *r* as it turns round, and makes the corn run out; *r* is a string going round the pin *s*, which serves to bring the spout nearer or let it go farther from the axis, and thus makes the corn to run faster or slower according to the velocity of the wind. If the wind be very strong, only part of the sails S, T, V, W, is covered, or perhaps only one half of the two opposite sails. Another cog-wheel B is placed towards the end B of the axle tree, with a trundle and mill-stones like those already described; so that when the wind is strong, the mill may do twice the business it ordinarily does. When only one pair is to grind, the trundle EF and axis G *t* are taken out from the other: *xyz* is a girt of pliable wood, fixed at the end *x*; and the other end *z* is tied to the lever *km*, moveable about *k*; and the end *m* being put down, draws the girt *xyz* close to the cog-wheel; and thus the motion of the mill may be stopped at pleasure: *pq* is a ladder for ascending to the higher part of the mill; and the corn is drawn up by means of a rope rolled about the axis AB.

63
A threshing
mill.

Besides these mills for grinding corn, one has lately been invented by a Mr Winlaw for threshing it out, and for which he has obtained a patent. It is represented fig. 95. A A A A represents the frame of the

Mills.

mill, B the cone, C a large iron wheel, D a regulating screw, E a pinion, G the top curb surrounding the nut, H the fly.

Before the corn is put into this mill, it must undergo the operations of combing the bottoms of the sheaves, and stripping the ears from the straw. The former is performed by means of an hand-comb. The use is obvious, viz. to take out all the loose ears, and straw laid irregularly, which would otherwise be lost, or impede the stripping of the ears. The comb for stripping the ears is made in the form of a cross. The teeth are of an angular form, and set at convenient distances, so as to strip the ears clean. If set too wide, they will pass through without effect; and if too near together, they will not admit the straw to go between them.

The grain is separated from the chaff and straw of the ear by the motion of the inner nut within the outward cope. The distance betwixt these is adjusted by the regulating screw D at the bottom; for if this be screwed up too far, the grain will be bruised, if too far lowered down, the grain will not be separated. The dart marked upon the fly shows the direction in which the handle is to be turned, it being pointed as the handle is to be turned.

This mill was tried in the month of June 1785, in the presence of a number of gentlemen, with great satisfaction to the spectators; and since that time has been used by a number of others, though it has not as yet come into general use. At the first trial three passed through the mill one bushel of heads per minute, with very moderate labour to the man who turned it; and by experiment it was found, that four bushels of ears yielded one bushel of clean grain. Hence it appears, that the difference betwixt the expedition of the mill and the labour of the thresher is immensely great; for allowing that a man will thresh six bushels per day at eight hours work, the mill will clear that quantity in 24 minutes, and that to much greater perfection than can be done by the flail, as it separates every grain from the ear, which cannot but be accounted a very great saving; while much corn flies off by the flail, and a great deal is lost by foul threshing, either when performed by talk or day-work. But by the use of the mill, all fraudulent practices must be prevented, the straw preserved in its original reed, and thus answer the purposes of thatching, &c. much better than when bruised under the flail; and every other purpose equally well. The ears may also be combed out with great expedition, as a lad without having practised was found to comb out a bushel of ears in 20 minutes, which is at the rate of six bushels of clean corn per day. The saving by the use of this mill is calculated at 2½d. per bushel. On a smaller scale the mill answers equally well for clover-seed, the flowers being first combed off from the stems; after which it will do as much work in three hours, as a man in the ordinary way can perform in a week; for a man cannot clean much above a bushel in that time, which is the great reason of the high price of clover-seed. The mill will likewise answer for flax, canary, or any other seeds, or for separating the husks from rice, which in the present mode cannot be done without great labour and expence.

In all mills it is necessary that a considerable power be

Mills.

be employed in order to accomplish the intended purpose.—Water is the most common power, and indeed the best, as being the most constant and equable; while wind comes at sometimes with great violence, and at others is totally gone. Mills may also be moved by the force of steam, as were the Albion-mills at London; but the expence of fuel must undoubtedly prevent this mode of constructing mills from ever becoming general. In all cases it is absolutely necessary to make the most of the power that we can, by making it act to the greatest advantage. Hence the best methods of constructing water and wind-mills have been investigated by those who were most conversant in the principles of mechanics; and so difficult has been the investigation, that the principles are not yet settled absolutely without dispute.

64
Different
kinds of
mills.

The water-mills are of three kinds: *Breast-mills, Under-shot-mills, and Over-shot-mills.* In the former, the water falls down upon the wheel at right angles, to the float-boards or buckets placed all round the wheel to receive it: if float-boards are used, it acts only by its impulse; but if buckets, it acts also by the weight of water in the buckets in the under quarter of the wheel, which is considerable. In the underhot wheel float-boards only are used, and the wheel is turned merely by the force of the current running under it, and striking upon the boards. In the overhot-wheel the water is poured over the top, and thus acts principally by its weight; as the fall upon the upper part of the wheel cannot be very considerable, lest it should dash the water out of the buckets. Hence it is evident, that an underhot-mill must require a much larger supply of water than any other; the breast-mill the next, unless the fall is very great; and an over-shot mill the least. Dr Desaguliers found, that a well-made overshot mill would perform as much work as an underhot one with one tenth part of the quantity of water required by the other.

65
Smeaton's
observations
on
mills.

In the 51st volume of the Philosophical Transactions, Mr Smeaton has considered at great length the best methods of constructing all these mills from machines and models made on purpose: but conscious of the inferiority of models to actual practice, did not venture to give his opinion without having seen them actually tried, and the truth of his doctrines established by practice.

Having described the machines and models used for making his experiments, he observes, that, with regard to power, it is most properly measured by the raising of a weight; or, in other words, if the weight raised be multiplied by the height to which it can be raised in a given time, the product is the measure of the power raising it; and, of consequence, all those powers are equal whose products made by such multiplication are equal: for if a power can raise twice the weight to the same height, or the same weight to twice the height in the same time that another can, the former power will be double the latter; but if a power can only raise half the weight to double the height,

or double the weight to half the height, in the same time that another can, the two powers are equal. This, however, must be understood only of a slow and equable motion, without acceleration or retardation; for if the velocity be either very quickly accelerated or retarded, the *vis inertia*, in our author's opinion, will produce an irregularity.

To compute the effects of water-wheels exactly, it is necessary to know in the first place what is the real velocity of the water which impinges on the wheel.

2. The quantity of water expended in a given time; and, 3. How much of the power is lost by the friction of the machinery.

1. With regard to the velocity of the water, Mr Smeaton determined by experiments with the machinery described in the volume referred to, that with a head of water 15 inches in height, the velocity of the wheel is 8.96 feet in a minute. The area of the head being 105.8 inches, this multiplied by the weight of a cubic inch of water equal to .579 of an ounce avoirdupoise, gives 61.26 ounces for the weight of as much water as is contained in the head upon one inch in depth: and by further calculations derived from the machinery made use of, he computes that 264.7 pounds of water descend in a minute through the space of 15 inches. The power of the water, therefore, to produce mechanical effects in this case will be 264.7×15 , or 3970. From the result of the experiment, however, it appeared that a vast quantity of the power was lost; the effect being only to raise 9.375 pounds to the height of 135 inches; so that the power was to the effect as 3970 to $9.375 \times 135 = 1266$, or as 10 to 3.18.

This, according to our author, must be considered as the greatest single effect of water upon an under-shot-wheel, where the water descends from an height of 15 inches; but as the force of the current is not by any means exhausted, we must consider the true proportion betwixt the power and effect to be that betwixt the quantity of water already mentioned and the sum of all the effects producible from it. This remainder of power, it is plain, must be equal to that of the velocity of the wheel itself multiplied into the weight of the water. In the present experiment, the circumference of the wheel moved with the velocity of 3.123 feet in a second, which answers to a head of 1.82 inches (A); and this height being multiplied by 264.7, the quantity of water expended in a minute gives 481 for the power of the water after it has passed the wheel; and hence the true proportion betwixt the power and the effect will be as 3849 to 1266; or as 11 to 4.

As the wheel revolved 86 times in a minute, the velocity of the water must be equal to 86 circumferences of the wheel; which, according to the dimensions of the apparatus used by Mr Smeaton, was as 86 to 30, or as 20 to 7.—The greatest load with which the wheel would move was 9 lb. 6 oz.; and by 12 lb. it was entirely stopped. Whence our author con-

5 D 2

cludes,

(A) These calculations are founded upon the known maxim in hydrostatics, that the velocity of spouting water is nearly the same with that which an heavy body would acquire by falling from an height equal to that of the reservoir, and is proved by the rising of jets nearly to the height of their reservoirs.

cludes, that the impulse of the water is more than than double of what it ought to be according to theory : but this he accounts for by observing, that in his experiment the wheel was placed not in an open river, where the natural current, after it has communicated its impulse to the float, has room on all sides to escape, as the theory supposes, but in a conduit, to which the float being adapted, the water cannot otherwise escape than by moving along with the wheel. It is observable, that a wheel working in this manner, as soon as the water meets the float, receiving a sudden check, it rises up against the float like a wave against a fixed object, inasmuch that when the sheet of water is not a quarter of an inch thick before the float, yet this sheet will act upon the whole surface of a float whose height is three inches : and consequently, was the float no higher than the thickness of the sheet of water, as the theory also supposes, a great part of the force would have been lost by the water dashing over the float.

Mr Smeaton next proceeds to give tables of the velocities of wheels with different heights of water ; and from the whole deduces the following conclusions.

1. The virtual, or effective head, being the same, the effect will be nearly as the quantity of water expended.

2. The expence of water being the same, the effect will be nearly as the height of the virtual or effective head.

3. The quantity of water expended being the same, the effect is nearly as the square of the velocity.

4. The aperture being the same, the effect will be nearly as the cube of the velocity of the water. Hence, if water passes out of an aperture in the same section, but with different velocities, the expence will be proportional to the velocity ; and therefore, if the expence be not proportional to the velocity, the section of the water is not the same.

5. The *virtual head*, or that from which we are to calculate the power, bears no proportion to the head water ; but when the aperture is larger, or the velocity of the water less, they approach nearer to a coincidence : and consequently, in the large openings of mills and sluices, where great quantities of water are discharged from moderate heads, the head of water, and virtual head determined from the velocity, will nearly agree, which is also confirmed by experience.

6. The most general proportion betwixt the power and effect is that of 10 to 3 ; the extremes 10 to 3.2, and 10 to 2.8. But as it is observable, that where the power is greatest, the second term of the ratio is greatest also ; whence we may allow the proportion subsisting in great works to be as three to one.

7. The proportion of velocity between the water and wheel is in general about 5 to 2.

8. There is no certain ratio between the load that the wheel will carry at its *maximum*, and what will totally stop it ; though the proportions are contained within the limits of 20 to 19, and 20 to 15 ; but as the effect approaches nearest to the ratio of 20 to 15, or of 4 to 3 when the power is greatest either by increase of velocity or quantity of water, this seems to be the most applicable to large works : but as the load that a wheel ought to have, in order to work to the

best advantage, can be assigned by knowing the effect that it ought to produce, and the velocity it ought to have in producing it, the exact knowledge of the greatest load it will bear is of the least consequence in practice.

Mr Smeaton, after having finished his experiments on the underhot mills, reduced the number of floats, which were originally 24, to 12 ; which caused a diminution in the effect, by reason that a greater quantity of water escaped between the floats and the floor than before ; but on adapting to it a circular sweep of such a length, that one float entered into the curve before the other left it, the effect came so near that of the former, as not to give any hopes of advancing it by increasing the number of floats beyond 24 in this particular wheel.

Our author next proceeds to examine the power of water when acting by its own gravity in turning an overhot wheel : " In reasoning without experiment (says he,) one might be led to imagine, that however different the mode of application is, yet that, whenever the same quantity of water descends through the same perpendicular space, the natural effective power would be equal, supposing the machinery free from friction, equally calculated to receive the full effect of the power, and to make the most of it : for if we suppose the height of a column of water to be 30 inches, and resting upon a base or aperture of one inch square, every cubic inch of water that departs therefrom will acquire the same velocity or momentum from the uniform pressure of 30 cubic inches above it, that one cubic inch let fall from the top will acquire in falling down to the level of the aperture ; one would therefore suppose that a cubic inch of water let fall through a space of 30 inches, and there impinging upon another body, would be capable of producing an equal effect by collision, as if the same cubic inch had descended through the same space with a slower motion, and produced its effects gradually. But however conclusive this reasoning may seem, it will appear in the course of the following deductions, that the effect of the gravity of descending bodies is very different from the effect of the stroke of such as are non-elastic, though generated by an equal mechanical power."

Having made such alterations in his machinery as were necessary for overhot wheels, our author next gives a table of experiments with the apparatus so altered. In these the head was 6 fix inches, and the height of the wheel 24 inches ; so that the whole descent was 30 inches : the quantity of water expended in a minute was 96½ pounds ; which multiplied by 30 inches, gives the power = 2900 : and after making the proper calculations, the effect was computed at 1914 ; whence the ratio of the power to it comes to be nearly as 3 to 2. If, however, we compute the power from the height of the wheel only, the power will be to the effect nearly as 5 to 4.

From another set of experiments the following conclusions were deduced.

1. The effective power of the water must be reckoned upon the whole descent ; because it must be raised to that height in order to be able to produce the same effect a second time. The ratios between the powers

Mills.

powers so estimated and the effects at a *maximum*, differ nearly from 4 to 3, and from 4 to 2. Where the heads of water and quantities of it expended are the least, the proportion is nearly from 4 to 3; but where the heads and quantities are greatest, it comes nearer to that of 4 to 2; so that by a medium of the whole the ratio is nearly as 3 to 2. Hence it appears, that the effect of overhot wheels is nearly double to that of underhot ones; the consequence of which is, that non-elastic bodies, when acting by their impulse or collision, communicate only a part of their original impulse, the remainder being spent in changing their figure in consequence of the stroke. The ultimate conclusion is, that the effects as well as the powers are as the quantities of water and perpendicular heights multiplied together respectively.

2. By increasing the head, it does not appear that the effects are at all augmented in proportion; for by raising it from 3 to 11 inches, the effect was augmented by less than one-seventh of the increase of perpendicular height. Hence it follows, that the higher the wheel is in proportion to the whole descent, the greater will be the effect; because it depends less upon the impulse of the head, and more upon the gravity of the water in the buckets: and if we consider how obliquely the water issuing from the head must strike the buckets, we shall not be at a loss to account for the little advantage that arises from the impulse thereof, and shall immediately see of how little consequence this is to the effect of an overhot wheel. This, however, as well as other things, must be subject to limitation; for it is necessary that the velocity of the water should be somewhat greater than the wheel, otherwise the latter will not only be retarded by the striking of the buckets against the water, but some of the power will be lost by the dashing of the water over the buckets.

3. To determine the velocity which the circumference of the wheel ought to have in order to produce the greatest effect, Mr Smeaton observes, that the more slowly any body descends by the force of gravity when acting upon any piece of machinery, the more of that force will be spent upon it, and consequently the effect will be the greater. If a stream of water falls into the bucket of an overhot wheel, it will be there retained till the wheel discharges it by moving round; and of consequence, the slower the wheel moves, the more water it will receive; so that what is lost in velocity is gained by the greater pressure of water upon the buckets. From the experiments, however, it appears, that when the wheel made about 20 turns in a minute the effect was greatest; when it made only 18 $\frac{1}{2}$ the motion was irregular; and when loaded so as not to admit its turning 18 times, the wheel was overpowered with the load. When it made 30 turns, the power was diminished by about $\frac{1}{10}$ th, and when the number of turns was increased to 40, it was diminished by one-fourth. Hence we see, that in practice the velocity of the wheel should not be diminished farther than what will procure some solid advantage in point of power; because, *ceteris paribus*, the buckets must be larger as the motion is slower; and the wheel being more loaded with water, the stress will be proportionally increased upon every part of the work. The best velocity for practice therefore

Mills.

will be that when the wheel made 30 turns in a minute, which is little more than three feet in a second. This velocity is applicable to the highest overhot wheels as well as the lowest. Experience however determines, that high wheels may deviate further from this rule before they will lose their power, by a given aliquot part of the whole, than low ones can be permitted to do; for a wheel of 24 feet high may move at the rate of 6 feet *per* second; while our author has seen one of 33 feet high move very steadily and well with a velocity of little more than two feet. The reason of this superior velocity in the 24 feet wheel, may probably be owing to the small proportion that the head requisite to give the proper velocity to the wheel bears to the whole height.

4. The maximum load for an overhot wheel is that which reduces the circumference of the wheel to its proper velocity; which is known by dividing the effect it ought to produce in a given time by the space intended to be described by the circumference of the wheel in the same time: the quotient will be the resistance overcome at the circumference of the wheel, and is equal to the load required, including the friction and resistance of the machinery.

5. The greatest velocity that an overhot wheel is capable of, depends jointly upon the diameter or height of the wheel and the velocity of falling bodies; for it is plain that the velocity of the circumference can never be greater than to describe a semi-circumference, while a body let fall from the top describes the diameter, nor even quite so great; as the difference in point of time must always be in favour of that which falls through the diameter. Thus, supposing the diameter of the wheel to be 16 feet and an inch in diameter, an heavy body would fall through this space in one second; but such a wheel could never arrive at this velocity, or make one turn in two seconds, nor could an overhot wheel ever come near it; because, after it has acquired a certain velocity, great part of the water is prevented from entering the buckets, and part is thrown out again by the centrifugal force: and as these circumstances have a considerable dependence upon the form of the buckets, it is impossible to lay down any general rule for the velocity of this kind of wheels.

6. Though in theory we may suppose a wheel to be made capable of overcoming any resistance whatever, yet as in practice it is necessary to make the wheel and buckets of some certain and determinate size, we always find that the wheel will be stopped by such a weight as is equal to the effort of the water in all the buckets of a semi-circumference put together. This may be determined from the structure of the buckets themselves; but in practice, an overhot wheel becomes unserviceable long before this time; for when it meets with such an obstacle as diminishes its velocity to a certain degree, its motion becomes irregular; but this never happens till the velocity of the circumference is less than the two feet *per* second, when the resistance is equal.

7. From the above observations, we may easily deduce the force of water upon breast-wheels, &c. But in general, all kinds of wheels where the water cannot descend through a given space unless the wheel moves with it, are to be considered as overhot wheels; and those

those which receive the impulse or shock of the water, whether in an horizontal, oblique, or perpendicular direction, are to be considered as undershots. Hence a wheel in which the water strikes at a certain point below the surface of the head, and after that descends in the arch of a circle, pressing by its gravity upon the wheel, the effect of such a wheel will be equal to that of an undershot whose head is equal to the difference of level between the surface of the water in the reservoir and the point where it strikes the wheel, added to that of an overshoot, whose height is equal to the difference of level between the point where it strikes the wheel and the level of the tail-water.

66
Dispute
concerning
Sir Isaac
Newton's
doctrine of
motion con-
sidered.

In the 66th volume of the Transactions, our author considers some of the causes which have produced disagreements and disputes among mathematicians upon this subject. He observes, that soon after Sir Isaac Newton had given his definition, "that the quantity of motion is the measure of the same, arising from the velocity and quantity of matter conjointly," it was controverted by his cotemporary philosophers. They maintained, that the measure of the quantity of motion should be estimated by taking the quantity of matter and the square of the velocity conjointly. On this subject he remarks, that from equal impelling powers acting for equal intervals of time, equal augmentations of velocity are acquired by given bodies when they are not resisted by a medium. Thus a body descending one second by the force of gravity, passes through a space of 16 feet and an inch; but at the end of that time it has acquired a velocity of 32 feet 2 inches in a second; at the end of two seconds, it has acquired one that would carry it through 64 feet 4 inches in a second. If, therefore, in consequence of this equal increase of velocity, we define this to be a double quantity of motion generated in a given time in a certain quantity of matter, we come near to Sir Isaac's definition: but in trying experiments upon the effects of bodies, it appears, that when a body is put in motion by whatever cause, the impression it will make upon an uniformly resisting medium, or upon uniformly yielding substances, will be as the mass of matter of the moving body multiplied by the square of its velocity. The question therefore properly is, whether those terms, the *quantity of motion*, the *momenta*, or *forces* of bodies in motion, are to be esteemed equal, double, or triple, when they have been generated by an equable impulse acting for an equal, double, or triple time? or that it should be measured by the effects being equal, double, or triple, in overcoming resistances before a body in motion can be stopped? For according to the meaning we put upon these words, the momenta of equal bodies will be as the velocities or squares of the velocities of the moving bodies.

Though by a proper attention to the terms employed, however, we will find both these doctrines to be true; it is certain that some of the most celebrated writers upon mechanics have fallen into errors by neglecting to attend to the meaning of the terms they make use of. Defaguliers, for instance, after having been at pains to show that the dispute, which in his time had subsisted for 50 years, was a dispute merely about words, tells us, that both opinions may be easily reconciled in the following case, viz. that the

wheel of an undershot water-mill is capable of doing quadruple work when the velocity of the water is doubled, instead of double work only: "For (says he) the adjuantage being the same, we find, that as the water's velocity is double, there are twice the number of particles that issue out, and therefore the ladle-board is struck by twice the matter; which matter moving with twice the velocity that it had in the first case, the whole effect must be quadruple, though the instantaneous stroke of each particle is increased only in a simple proportion of the velocity." In another place, the same author tells us, that though "the knowledge of the foregoing particulars is absolutely necessary for setting an undershot wheel to work, yet the advantage to be reaped from it would be still guess-work; and we should be at a loss to find out the utmost that it could perform, had it not been for an ingenious proposition of that excellent mechanic M. Parent of the Royal Academy of Sciences, who has showed, that an undershot wheel can do the most work when its velocity is equal to the third part of that of the water; because then two-thirds of the water is employed in driving the wheel, with a force proportionable to the square of the velocity. By multiplying the surface of the adjuantage or opening by the height of the water, we shall have the column of water that moves the wheel. The wheel thus moved will sustain on the opposite side only four-ninths of that weight which will keep it in equilibrio; but what it can move with the velocity it has, is only one-third of the equilibrium." This conclusion is likewise adopted by Mr Maclaurin.

Undershot wheels had been greatly preferred by M. Belidor to those of any other construction. He had even concluded, that water applied in this way will do more than six times the work of an overshoot wheel; while Dr Defaguliers, in overthrowing Belidor's proposition, determined that an overshoot wheel would do 10 times the work of an undershot wheel with an equal quantity of water. Between these two celebrated authors, therefore, there is a difference of no less than 60 to 1.

In consequence of such monstrous disagreement, Mr Smeaton began the experiments of which we have already given an account. From them, besides the positions already deduced, it appears, that where the velocity of water is double, the adjuantage or aperture of the sluice remaining the same, the effect is eight times; that is, not as the square, but as the cube of the velocity. In the other conclusion of Defaguliers and Maclaurin, the error was no less; for from thence it would follow, that by means of the wheel only $\frac{1}{27}$ ths of the water expended would be raised back again to the height of the reservoir from which it descended, exclusive of the friction, which would still diminish the quantity; but from Mr Smeaton's experiments it appears, that in some cases upwards of one-fourth had been raised. In large works the effects had been still greater, approaching in an undershot wheel to one half, and in an overshoot one to the whole; which would be the limit, if it were possible, to remove the friction and resistance of the air. The velocity of the wheel also, which, according to the conclusions of M. Parent and Dr Defaguliers, amounted to no more than one-third of the velocity of the water,

67
Enormous
mistakes of
Belidor
and others.

ter, varies, according to Mr Smeaton, between one-third and one-half. But in all great works the maximum lieth much nearer to one-half than a third; the former appearing to be the true maximum, if all friction, resistance of the air, and scattering of water, could be avoided.

To make these matters plain to mechanics, and to prevent them from running into practical errors in consequence of a fallacious theory, Mr Smeaton, in the year 1759, instituted another set of experiments; the immediate object of which was, to determine what proportion or quantity of mechanical power is expended in giving the same body different degrees of velocity. Having constructed a proper apparatus for the purpose, and with it made a number of experiments, he concludes, "that time, properly speaking, has nothing to do with the production of mechanical effects otherwise than as by equally flowing it becomes a common measure; so that whatever mechanical effect is found to be produced in a given time, the uniform continuance of the action of the same mechanical power will, in a double time, produce twice that effect. A mechanical power, therefore, properly speaking, is measured by the whole of its mechanical effects produced, whether that effect be produced in a greater or lesser time: thus, having treasured up 1000 tons of water, which I can let out upon the overshot wheel of a mill, and descending through a perpendicular of 20 feet; this power, applied in a proper manner, will grind a certain quantity of corn in an hour: but supposing the mill to be capable of receiving a greater impulse with as great advantage as a lesser; then, if the corn be let out twice as fast, the same quantity of water will be ground in half an hour, the whole of the water being likewise expended in that time. What time has therefore to do in the case is this: let the rate of doing the business or producing the effect be what it will; if this rate is uniform, when I have found by experiment what is done in a given time, then, proceeding at the same rate, twice the effect will be produced in twice the time, on supposition that I have a supply of mechanic power to go on with. Thus, 1000 tons of water descending through 20 feet perpendicular, being, as has been shown, a given mechanic power, let it be expended at what rate it will; if, when this is expended, we are to wait another hour till an equal quantity can be procured, then we can only expend 12 such quantities in 24 hours. But if, while the thousand tons of water are expending in one hour, the same quantity is renewed, we can then expend 24 such in the 24 hours, or go on without intermission. The product or effect will then be in pro-

portion to time; which is the common measure; but the quantity of mechanic power arising from the flow of the two rivers, compared by taking an equal portion of time, is double in the one to the other; though each has a mill that, when going, will grind an equal quantity of corn in an hour."

Mr Ferguson, in his directions to mill-wrights, has adopted the maxim which Mr Smeaton condemns as erroneous, viz. that when the velocity of the wheel is but one-third of that of the water, it then acts to the greatest advantage. He adds, that the millstone ought to make about 60 turns in a minute; for when it makes only 40 or 50 turns it grinds too slowly; and when more than 70, it heats the meal too much, and cuts the bran so small, that a part of it mixes with the meal and cannot be separated from it by any means. The utmost perfection of mill-work, therefore, according to this author, lies in making the train so that the millstone shall make about 60 turns in a minute, when the wheel moves with one-third of the velocity of the water. To accomplish this he lays down the following rules. 1. Measure the perpendicular height of the fall of water above the middle of the aperture, where it is let out to act by impulse against the float-boards on the lower side of the undershot wheel. 2. Multiply this constant number 64.2882 by the height of the fall in feet, and extract the square-root of the product, which will give the number of feet that the water moves in a second. 3. The velocity of the floats of the wheel is equal to one-third of the velocity of the water just now found. 4. Divide the circumference of the wheel by the velocity of its floats, and the quotient will be the number of seconds in one turn of the great water-wheel, on whose axis the cog-wheel that turns the trundle is fixed. 5. Divide 60 by the number of seconds in a turn of the water-wheel, and the quotient will be the number of turns it makes in a minute. 6. By this number of turns divide 60, the number of times that a millstone ought to have in a minute; the quotient is the number of turns that the millstone ought to make for every one of the large wheel. 7. Then as the number of turns required of the millstone in a minute is to the number of turns of the cog-wheel in a minute; so must the number of cogs in the wheel be to the number of flaves in the trundle on the axis of the millstone, in the nearest whole number that can be found.

On these principles Mr Ferguson has constructed the following table, for the sake of such as have occasion to construct mills, and are not willing to take the trouble of particular calculations.

The Mill-wright's TABLE.

Height of the fall of water.	Velocity of the fall of water per second.	Velocity of the wheel per second.	Revolutions of the wheel per minute.	Revolution of the millstone for one of the wheel	Cogs in the wheel, and flaves in the trundle.	Revolutions of the millstone per minute by these flaves and cogs.
Fect.	100 parts of a foot. Fect.	100 parts of a foot. Fect.	100 parts of a rev. Revolutions.	100 parts of a rev. Revolutions.	Cogs. Slaves.	100 parts of a rev. Revolutions.

Imison's
practical
rules for
the con-
struction
of mills.

For the practical construction of water-mills, Mr Imison hath laid down the following rules.

1. To find the velocity or force of any moderate stream of water; let it be obstructed by a dam in such a manner as to force the whole stream into a spout by which it may be conveyed into a large vessel or reservoir. Measure then the quantity of water which falls into the reservoir in one second or minute; and multiplying by the number of seconds or minutes in an hour, we have the whole force of the stream of water per hour. In streams which are too large to be measured in this way, the velocity is determined (though we must own in a vague manner) by that of flax or other light body floating down it; and calculations may be made accordingly.

Mr Imison differs very materially from Mr Ferguson in the number of revolutions which a mill-stone ought to make in a minute; the latter, as has been already mentioned, being of opinion, that 60 revolutions of a mill-stone in a minute are sufficient, while Mr Imison requires 120; though he agrees with him that the velocity of the wheel should be only one-third of that of the water. The mill-stone, according to Mr

N^o 200.

Ferguson, ought to be five feet in diameter; but Mr Imison makes it only four feet and an half.

To construct a mill by this table, find the height of the fall of water in the first column, and against that height in the sixth column you have the number of cogs in the wheel and flaves in the trundle for causing the millstone 4 feet 6 inches diameter to make about 120 revolutions in a minute, as near as possible, when the wheel goes with one-third part of the velocity of the water. And it appears by the 7th column, that the number of cogs in the wheel and flaves in the trundle are so near the truth for the required purpose, that the least number of revolutions of the mill-stone in a minute is 118, and the greatest number never exceeds 121; which, according to our author, is the velocity of the best mills he had seen.

With regard to the mere mechanical part, our author observes, that an overshot wheel acts with greater power than a breast or under-shot wheel; so that where there is a considerable descent, and only a small quantity of water, the overshot wheel ought always to be made use of. Where the water runs only upon a little declivity, it can act but slowly upon the under part of the

Mills.

Mills.

the wheel; in which case, the motion of the wheel will be very slow: the float-boards therefore ought to be very long, though not high, that a large body of water may act upon them; so that what is wanting in velocity may be made up in power: in which case, the cog wheel may have a greater number of cogs in proportion to the staves of the trundle, in order to give the mill-stone a sufficient degree of velocity.

For the construction of the different parts of mills, Mr Imison gives the following general directions :

The method for setting out a four-wheel and wallower.

—Draw the pitch lines $A_1, B_1, A_2, 2B$; then divide them into the number of teeth or cogs required, as *abc*.

Divide one of those distances, as bc , into seven equal parts, as 1, 2, 3, 4, 5, 6, 7: three parts allow for the thickness of the cog, as 1, 2, 3, in the cog a , and four for the thickness of the flave, of the wallower (or reason for allowing three parts for the cog and four for the flave, is, the wallower is in general of less diameter than the wheel, therefore subject to more wear in proportion of the number of cogs to the number of flaves; but if there is the same number of flaves as of cogs, they may be of equal thickness), as 1, 2, 3, 4, in the flave m , fig. 97. the height of the cog is equal to four parts; then divide its height into five equal parts, as 1, 2, 3, 4, 5, in the cog C ; allow three for the bottom to the pitch line of the cog; the other two parts for epicycloid, so as to fit and bear on the flave equally. The mill-wrights in general put the point of a pair of compasses in the dot 3, of the cog a , and strike the line de ; then remove the point of the compasses to the point d , and strike the curve line $3f$, which they account near enough the figure of the epicycloid.

The method for a face-wheel is thus: Divide the pitch line AB into the number of cog intended, as abc ; divide the distance bc into seven equal parts; three of those parts allow for the thickness of the cog, as 1, 2, 3, in the cog a , four for the height and four for the width, as de , and four for the thickness of the flange m ; draw a line through the centre of the cog, as the line AI at S: and on the point g describe the line de ; remove the compasses to the point A , and draw the line fg , which forms the shape of the cog; then shape the cog on the flides to a cycloid, as $defg$. But this method of setting out the shape of a cog is variable, according to the cycloid in different diameters of wheels.

In common spur-nuts, divide the pitch line A into twice as many equal parts as you intend teeth, as a, b, c, d, e , fig. 98.; with a pair of compasses opened to half the distance of any of those divisions, from the points $a1, c3, e5$, draw the femicircles a_2, c_2 and e_2 which will form the ends of the teeth. From the points $2, 4$, and 6 , draw the femicircles ghi , which will form the hollow curves for the spaces; but if the ends of the teeth were epicycloids, instead of femicircles, they would act much better.

The principle of bevel gear,—consists in two cones, rolling on the surface of each other, as the cone A and B revolving on their centres ab , ac ; if their bases are equal, they will perform their revolutions in one and the same time, or any other two points equally distant from the centre a , as d_1 , d_2 , d_3 , &c. will revolve in

the same times f_1, f_2, f_3 , &c. In the like manner, if the cones $afde$ be twice the diameters at the base de , as the cones $afce$ are; then if they turn about their centres, when the cone $afcd$ has made one revolution, the cone $afde$ will have made but half a revolution; or when $afcd$ has made two revolutions, $afde$ will have made but one, and every part equally distant from the centre a , as f_1, f_2, f_3 , &c. will have made two revolutions to r_1, r_2, r_3 , &c. and if the cones were fluted, or had teeth cut in them, diverging from the centre a to the bases dc, ef , they would then become bevel gear. The teeth at the point of the cone being small and of little use, may be cut off at E and F figs. 102, 103, as seen by fig. 104, where the upright shaft ab , with the bevel wheel cd , turns the bevel wheel ef with its shaft fg , and the teeth work freely into each other, as ab, fg , 105. The teeth may be made of any dimension, according to the strength required; and this method will enable them to overcome a much greater resistance, and work smoother than a face wheel and wallower of the common form can possibly do; besides, it is of great use to convey a motion in any direction, or to any part of a building, with the least trouble and friction.

The method of conveying motion in any direction, and proportioning or shaping the wheels thereto, is as follows: let the line *ab* represent a shaft coming from Fig. 106. a wheel; draw the line *ed* to intersect the line *ab*, in the direction that the motion to be conveyed is intended, which will now represent a shaft to the intended motion.

Again, suppose the shaft *ed* is to revolve three times, whilst the shaft *ab* revolves once, draw the parallel line *ii*, at any distance not too great, suppose one foot by a scale; then draw the parallel line *kk* at three feet distance, after which draw the dotted line *wX*, through the intersection of the shafts *ab* and *ed*, and likewise through the intersection of the parallel lines *ii* and *kk*, in the points *X* and *y*; which will be the pitch line of the two bevel wheels, or the line where the teeth of the two wheels act on each other, as may be seen fig. 107. where the motion may be conveyed in any direction.

The universal joint, as represented fig. 108. may be applied to communicate motion instead of bevel gear, where the speed is to be continued the same, and where the angle does not exceed 30 or 40 degrees, and the equality of motion is not regarded; for as it recedes from a right line, its motion becomes more irregular. This joint may be constructed by a cross, as represented in the figure; or with four pins fastened at right angles upon the circumference of a hoop or solid ball. It is of great use in cotton-mills, where the tumbling shafts are continued to a great distance from the moving power. But by applying this joint, the shafts may be cut into convenient lengths, by which it will be enabled to overcome greater resistance.

To describe the cycloid and epicycloid, of use in shaping the teeth of wheels, &c.—If a point or pencil *a* on the circumference of the circle *B* proceeds along the plane *aC* in a right line, and at the same time revolves round its centre, it will describe a cycloid.

And if the generating circle D moves along the circumference of another circle E, and at the same time turns round its centre, the point of contact will describe an epicycloid.

Mills.

Mills.

In the construction of wind-mills, Mr Smeaton has been at no less pains to explain the principles than in those which go by water. For this purpose he constructed a machine, of which a particular description is given in the 51st volume of the Philosophical Transactions. The general principle of this was, that by means of a determinate weight it carried round an axis with an horizontal arm, upon which were four small moveable sails. Thus the sails met with a constant and equable blast of air; and as they moved round, a string with a weight affixed to it was wound about their axis, and thus showed what kind of size or construction of sails answered the purpose best.

With this machine a great number of experiments were made; the results of which were as follow.

1. The sails set at the angle with the axis, proposed as the best by M. Parent and other geometricians, *viz.* 55° , was found to be the worst proportion of any that was tried.

2. When the angle of the sails with the axis was increased from 72° to 75° , the power was augmented in the proportion of 31 to 45; and this is the angle most commonly in use when the sails are planes.

3. Were nothing more requisite than to cause the sails acquire a certain degree of velocity by the wind, the position recommended by M. Parent would be the best. But if the sails are intended with given dimensions, to produce the greatest effects possible in a given time, we must, if planes are made use of, confine our angle within the limits of 72 and 75 degrees.

4. The variation of a degree or two, when the angle is near the best, is but of little consequence.

5. When the wind falls upon concave sails, it is an advantage to the power of the whole, though each part separately taken should not be disposed of to the best advantage.

6. From several experiments on a large scale, Mr Smeaton has found the following angles to answer as well as any. The radius is supposed to be divided into six parts; and $\frac{1}{6}$ th, reckoning from the centre, is called 1, the extremity being denoted 6.

No	Angle with that axis.	Angle with the plane of motion.
1	72°	18°
2	71	19
3	72	18 middle
4	74	16
5	$77\frac{1}{2}$	$12\frac{1}{2}$
6	83	7 extremity.

7. Having thus obtained the best method of *weathering* the sails, *i.e.* the most advantageous manner in which they can be placed, our author's next care was to try what advantage could be derived from an increase of surface upon the same radius. The result was, that a broader sail requires a large angle; and when the sail is broader at the extremity than near the centre, the figure is more advantageous than that of a parallelogram. The figure and proportion of enlarged sails, which our author determines to be most advantageous on a large scale, is that where the extreme bar is one-third of the radius or whip (as the workmen call it), and is divided by the whip in the proportion of 3 to 5. The triangular or loading sail is covered with board from the point downward of its

height, the rest as usual with cloth. The angles above mentioned are likewise the most proper for enlarged sails; it being found in practice, that the sails should rather be too little than too much exposed to the direct action of the wind.

Some have imagined, that the more sail the greater would be the power of the windmill, and have therefore proposed to fill up the whole area; and by making each sail a sector of an ellipsis, according to M. Parent's method, to intercept the whole cylinder of wind, in order to produce the greatest effect possible. From our author's experiments, however, it appeared, that when the surface of all the sails exceeded seven-eighths of the area, the effect was rather diminished than augmented. Hence he concludes, that when the whole cylinder of wind is intercepted, it cannot then produce the greatest effect for want of proper interstices to escape.

"It is certainly desirable (says Mr Smeaton), that the sails of windmills should be as short as possible; but it is equally desirable, that the quantity of cloth should be the least that may be, to avoid damage by sudden squalls of wind. The best structure, therefore, for large mills, is that where the quantity of cloth is the greatest in a given circle that can be: on this condition, that the effect holds out in proportion to the quantity of cloth; for otherwise the effect can be augmented in a given degree by a lesser increase of cloth upon a larger radius, than would be required if the cloth was increased upon the same radius.

8. The ratios between the velocities of windmill sails unloaded, and when loaded to their maximum, turned out very different in different experiments, but the most common proportion was as 3 to 2. In general it happened, that where the power was greatest, whether by an enlargement of the surface of the sails, or an increased velocity of the wind, the second term of the ratio was diminished.

9. The ratios between the least load that would stop the sails and the maximum with which they would turn, were confined betwixt that of 10 to 8 and 10 to 9; being at a medium about 10 to 8.3, and 10 to 9, or about 6 to 5; though on the whole it appeared, that where the angle of the sails or quantity of cloth was greatest, the second term of the ratio was less.

10. The velocity of windmill sails, whether unloaded or loaded, so as to produce a maximum, is nearly as the velocity of the wind, their shape and position being the same. On this subject Mr Ferguson remarks, that it is almost incredible to think with what velocity the tips of the sails move when acted upon by a moderate wind. He has several times counted the number of revolutions made by the sails in 10 or 15 minutes; and from the length of the arms from tip to tip, has computed, that if an hoop of the same size was to run upon plain ground with an equal velocity, it would go upwards of 30 miles in an hour.

11. The load at the maximum is nearly, but somewhat less, than as the square of the velocity of the wind; the shape and position of the sails being the same.

12. The effects of the same sails at a maximum are nearly, but somewhat less, than as the cubes of the velocity of the wind.

13. The load of the same sails at a maximum is nearly

Mills.

Mills.

nearly as the squares, and the effect as the cubes of their number of turns in a given time.

14. When sails are loaded so as to produce a maximum at a given velocity, and the velocity of the wind increases, the load continuing the same; then the increase of effect, when the increase of the velocity of the wind is small, will be nearly as the squares of these velocities; but when the velocity of the wind is double, the effects will be nearly as 10 to 27 $\frac{1}{2}$; and when the velocities compared are more than double of that where the given load produces a maximum, the effects increase nearly in a simple ratio of the velocity of the wind. Hence our author concludes, that windmills, such as the different species for draining water, &c. lose much of their effect by acting against one invariable opposition.

15. In sails of a similar figure and position, the number of turns in a given time will be reciprocally as the radius or length of the sail.

16. The load at a maximum that fails of a similar figure and position will overcome, at a given distance from the centre of motion, will be as the cube of the radius.

17. The effects of sails of similar position and figure are as the square of the radius. Hence augmenting the length of the sail without augmenting the quantity of cloth, does not increase the power; because what is gained by the length of the lever is lost by the slowness of the motion. Hence also if the sails are increased in length, the breadth remaining the same, the effect will be as the radius.

18. The velocity of the extremities of the Dutch sails, as well as of the enlarged sails, either unloaded or even when loaded to a maximum, is considerably greater than that of the wind itself. This appears plainly from the observations of Mr Ferguson already related concerning the velocity of sails, and is more fully treated of under the article WIND.

19. From many observations of the comparative effects of sails of various kinds, Mr Smeaton concludes, that the enlarged sails are superior to those of the Dutch construction.

Having thus discussed the subject of the common windmills with oblique vanes, our author next proceeds to the consideration of those called *horizontal* windmills, in which it is attempted to make the wind impinge directly upon the wheel, as in the case of water-mills. To set the probable advantage of this scheme in its proper point of view, Mr Smeaton proceeds in the following manner: "Let AB, fig. 111. be the section of a plane, in which let the wind blow in the direction CD, with such a velocity as to describe a given space BE, in a given time, suppose one second; and let AB be moved parallel to itself in the direction CD. Now, if the plane AB moves with the same velocity as the wind; that is, if the point B moves through the space BE in the same time that a particle of air would move through it, it is plain, that in this case there can be no pressure or impulse of the wind upon the plane; but if the plane moves slower than the wind, so that the point B may move to F, while a particle of air setting out from B would reach E, then BF will express the velocity of the plane; and the relative velocity of the wind and plane would be expressed by the line FE. Let the ratio of FE to BE be

given, suppose 2 to 3; let the line AB represent the impulse of the wind upon the plane AB when acting with its whole velocity BE; but when acting with its relative velocity FE, let its impulse be denoted by some aliquot part of AB, as for instance $\frac{2}{3}$; then will $\frac{2}{3}$ ths of the parallelogram AF represent the mechanical power of the plane, that is, $\frac{2}{3}$ ths AB \times $\frac{2}{3}$ BE.

"2. Let IN be the section of a plane inclined in such a manner, that the base IK of the right angled triangle IKN may be equal to AB; and the perpendicular NK=BE: let the plane IN be struck by the wind in the direction LM, perpendicular to IK; then, according to the known rules of oblique forces, the impulse of the wind upon the plane IN, tending to move it according to the direction LM or NK, will be denoted by the base IK; and that part of the impulse tending to move it, according to the direction IK, will be expressed by the perpendicular NK. Let the plane IN be moveable in the direction of IK only; that is, the point I in the direction of IK, and the point N in the direction NQ parallel thereto. Now it is evident, that if the point I moves through the line IK, while a particle of air, setting forwards at the same time from the point N, moves through the line NK, they will both arrive at the point K at the same time; and consequently there can be no pressure or impulse of the particle of air upon the plane IN. Now let IO be to IK as BF to BE; and let the plane IN move at such a rate, that the point I may arrive at O, and acquire the position OQ, in the same time that a particle of air would move through the space NK; as OQ is parallel to IN, by the properties of similar triangles, it will cut NK in the point P in such a manner, that NP will be equal to BF, and PK to FE. Hence it appears, that the plane IN, by acquiring the position OQ, withdraws itself from the action of the wind, by the same space NP that the plane AB does by acquiring the position FG; and consequently, from the equality of PK to FE, the relative impulse of the wind PK upon the plane OQ will be equal to the relative impulse of the wind upon the plane FG: and since the impulse of the wind upon AB, with the relative velocity FE, in the direction BE, is represented by $\frac{2}{3}$ AB; the relative impulse of the wind upon the plane IN in the direction NK will in like manner be represented by $\frac{2}{3}$ IK; and the impulse of the wind upon the plane IN, with the relative velocity PK, in the direction IK will be represented by $\frac{2}{3}$ NK: and consequently the mechanical power of the plane IN in the direction IK will be represented by $\frac{2}{3}$ of the parallelogram IQ; that is, $\frac{2}{3}$ IK \times $\frac{2}{3}$ NK: that is, from the equality of IK to AB, and NK to BE, we shall have $\frac{2}{3}$ IQ= $\frac{2}{3}$ AB \times $\frac{2}{3}$ BE= $\frac{2}{3}$ AB \times $\frac{2}{3}$ BE= $\frac{2}{3}$ the area of the parallelogram AF.

"Hence we deduce this general proposition; that all planes, however situated, that intercept the same section of the wind, and having the same relative velocity in regard to the wind, when reduced into the same direction, have equal powers to produce the same mechanical effects. For what is lost by the obliquity of the impulse, is gained by the velocity of the motion.

"Hence it appears, that an oblique sail is under no disadvantage in respect of power, compared with a direct one; except what arises from a diminution of its

breadth, in regard to the section of the wind; the breadth IN being by obliquity reduced to IK.

"The disadvantage of horizontal windmills therefore does not consist in this, that each sail, when directly exposed to the wind, is capable of a less power than an oblique one of the same dimensions; but that in an horizontal windmill little more than one sail can be acting at once: whereas, in the common windmill, all the four act together; and therefore, supposing each vane of an horizontal windmill to be of the same size with that of a vertical one, it is manifest that the power of a vertical mill will be four times as great as that of an horizontal one, let the number of vanes be what we will. This disadvantage arises from the nature of the thing; but if we consider the further disadvantage that arises from the difficulty of getting the sails back again against the winds, &c. we need not wonder if this kind of mill is in reality found to have not above one-eighth or one-tenth of the power of the common sort; as has appeared in some attempts of this kind."

Notwithstanding what is here advanced, it seems that the ideas of Mr Smeaton have not been very generally received, as premiums are still held forth for the best methods of constructing horizontal wind-mills. Indeed, considering the clearness and perspicuity of the above reasoning, it seems surprising that public encouragement should continue to be given to attempts which must certainly prove abortive. The principal inconvenience in wind-mills is their excessive irregularity and difficulty of being managed when the wind is high, owing to the great extent of the sails and bulk of the machinery. But were it possible to make a number of small wind-mills exert their power upon one object, these would be much more easily managed than one large one. Perhaps if a number of these were to be employed in pumping up water to a certain height from a lake or reservoir, so as to produce a constant stream of water to turn a common mill, it might be more advantageous than to employ them directly. Wind-mills are commonly erected upon eminences for the sake of receiving the wind to more advantage; and there are few eminences which do not afford a small supply of water at no great distance from their summit. This supply being collected in a reservoir, might be drawn up to the top by pumps worked by wind-mills; where being collected in another reservoir, it might be let down to the former, turning a water-mill in its way, and being again drawn up by the pumps as before.

Some projectors, considering the great power of oblique vanes in wind-mills, have attempted to improve water-mills by giving them oblique vanes, but with as little success. The power of the same section of a stream of water is not greater when acting upon an oblique vane than on a direct one; and any advantage which can be made of intercepting a greater section of water, which sometimes may be done in the case of an open river, must be counterbalanced by the superior resistance that such vanes would meet with by moving at right angles to the current; whereas the common floats always move with the water nearly in the same direction.

Mr Smeaton concludes his dissertation upon this subject, with giving a reason why one angle should be

preferable to another in setting the sails of a wind-mill. "It is to be observed (says he), that if the breadth of the sail IN is given, the greater the angle KIN, the less will be the base IK; that is, the section of the wind intercepted will be less. On the other hand, the more acute the angle KIN, the less will be the perpendicular KN; that is, the impulse of the wind in the direction IK being less, and the velocity of the sail greater, the resistance of the medium will be greater also. Hence, therefore, as there is a diminution of the section of the wind intercepted on one hand, and an increase of resistance on the other, there is some angle where the disadvantage arising from these causes upon the whole is the least of all; but as the disadvantage arising from resistance is more of a physical than geometrical consideration, the true angle will best be assigned by experiment."

Motion of
Bodies.

SECT. VI. Of the Motion of Bodies in Straight Lines and Curves; the Acceleration, Accumulation, and Retardation, of Motion in various Circumstances.

To understand this subject, it is necessary to keep in mind what has been said concerning the *momentum* or quantity of motion in any moving body, viz. that it is compounded of the velocity multiplied into the quantity of matter. Thus, suppose there are two bodies, one containing twice the quantity of matter contained in the other, but moving with thrice its velocity, the quantities of matter will be expressed by any numbers in the proportion of 2 to 1, and their velocities by any others in the proportion of 3 to 1. Multiplying therefore the quantity of matter in the first (2) by its velocity (3), the product is 6; and multiplying the quantity of matter (1) by its velocity (1), the product is only 1; whence it appears that the momenta or absolute forces of these bodies are to one another as 6 to 1.

As some bodies are elastic and others non-elastic, the effect of motion communicated from one to another becomes very different, according to this circumstance. The motion is likewise very different, according to the manner in which one body acts upon another, and according to which it will be driven forward in a rectilinear direction, or describe curves of various kinds, revolving on its axis, &c. These different kinds of motion have been considered by different authors, but by none more particularly than Mr G. Atwood, who has published a large octavo volume upon the rectilinear motion and rotation of bodies. The fundamental laws of motion assumed by this author as axioms are three.

1. Every body perseveres in its state of rest or uniform motion in a right line, until a change is effected by the agency of some external force.

2. Any change effected in the quiescence or motion of a body is in the direction of the force impressed, and is proportional to it in quantity.

3. Action and reaction are equal, and in contrary directions.

From these three simple axioms, the truth of which must, from what has been already said, be abundantly evident, our author proceeds to demonstrate the most difficult problems concerning the impulse and motion

of

Motion of
Bodies.

of bodies in every possible direction, beginning from the most simple and easy deductions. For the more easy comprehending this subject, however, we shall premise what our author has said in his second section concerning the properties of *ratios* or proportions.

1. Two mathematical quantities of the same kind, as two lines, two surfaces, two angles, &c. constitute a ratio. Thus, suppose one line two feet in length and another four; these are to one another in the ratio of 4 to 2, or of 2 to 1; but a line cannot be said to bear any ratio to a surface, because they are not quantities of the same kind, and therefore cannot be compared.

2. We may compare the ratio of two quantities of one kind with the ratio of two quantities of a different kind. Thus, when two bodies move uniformly, for an equal time, but with different velocities, the ratio of the spaces passed over may be compared with that of the velocities, though space and velocity are accounted different quantities.

3. If any quantity be divided by another of the same kind, the quotient becomes absolute number. Thus, if we divide a velocity of four feet in a second by one of two feet in a second, the quotient will be 2; and in all cases the quotient will be to 1 as the greater quantity is to the lesser.

4. The ratio of any mathematical quantities may be expressed by two numbers, if both terms of the ratio be divided by the consequent or by the antecedent. Thus, let the antecedent be 8 and the consequent 4; let both be divided by 4, and the ratio will then be 2 to 1; or let both be divided by 8, and it will be 1 to 0.5, which is the same.

5. Any ratio may be represented by a fraction, the numerator of which is the antecedent, and the denominator the consequent. Thus the ratio of 8 to 4 is represented by the fraction $\frac{8}{4}$; and hence we may add and subtract ratios by the addition and multiplication of fractions. Thus, supposing two bodies to move uniformly, one at the rate of 8 feet in a second and the other 4; supposing them also to move the former for four, and the latter for two seconds, the spaces passed over will be 32 and 8, their ratio $\frac{32}{8}$, or at length $32:8::4\times8:2\times4$; or $\frac{1}{2}=\frac{2}{4}\times\frac{1}{2}$. Here it is to be observed, that when the mark of equality is interposed betwixt heterogeneous quantities, the only equality meant is that which subsists between the ratios there expressed; and when the mark of multiplication is interposed between heterogeneous quantities, it means the addition of two ratios, the antecedents of which are the terms expressed, and the consequents are unity.

6. If there are three ratios, consisting of variable terms, and the relation of the quantities to each other be such, that when the third ratio becomes unity the other two become equal; or when the second becomes unity, the first and third are equal; then in all cases, whatever be the magnitudes, we have the first ratio $=$ the 2d \times 3d. Thus let the three ratios be $\frac{1}{2}$, $\frac{2}{3}$, and $\frac{3}{4}$, diminishing the numbers by 1, we have $\frac{1}{3}$, $\frac{2}{4}$, and $\frac{3}{5}$; it is evident that $\frac{1}{3}=\frac{2}{4}\times\frac{3}{5}$; the same will be the case if we place them in a different order, as $\frac{1}{4}$, $\frac{2}{3}$, and $\frac{3}{5}$; for then, diminishing as before, we have $\frac{1}{5}$, $\frac{2}{4}$, and $\frac{3}{5}$, in which case $\frac{1}{5}=\frac{2}{4}\times\frac{3}{5}$.

7. In comparing the ratios which obtain between

 Motion of
Bodies.

mathematical quantities of any sort, the standard to which each of those quantities is referred may be taken $=$ 1. Thus, supposing we compare the weight, magnitude, and density, of any substance with water, we may take a cubic inch of that element for a standard, and call the weight, magnitude, and density of it $=$ 1; by which means we may readily compare the weight, magnitude, or density, of any quantity, however large, of another substance with water.

We now proceed to that part of the work which treats directly of the motion of bodies acted upon by any external impulse.

8. Any force acting continually upon a body in the same direction, will produce a continual acceleration or retardation of the motion. Thus, if a body descends by the force of gravity, its motion is continually accelerated; or if it be thrown up against the force of gravity, the motion will be continually retarded until it be totally destroyed.

9. If, while a body moves, equal quantities of motion be communicated to it, or taken from it in equal spaces of time, the force is said to be constant, and equally accelerated or retarded.

10. When unequal velocities are generated or destroyed in equal spaces of time, the force is said to be variable.

11. When a body is acted upon by a constant force, we must consider the space through which it moves, the time it takes to move through it, the velocity it acquires, and the force which produces it; any two of which being given, we may from them find the other two. Here we must observe, that the force mentioned relates only to the communication of the velocity, without any regard to the quantities of matter moved. As it is proportioned to the velocity generated in a given time, it is thence called the *accelerating* force. That which relates to the quantity of matter moved, as well as the velocity communicated, is called the *moving* force; being proportional to the quantity of motion produced in a given time.

12. The moving forces which communicate the same velocity in a given time to different bodies, will be as the quantities of matter contained in the bodies moved. This will appear from a consideration of what has already been said concerning the momenta of bodies. For if one body contains ten times the quantity of matter that another does, it will of course require ten times as much force to move it with an equal degree of velocity; for the former is equivalent to ten such bodies, and it is the same thing whether they be separate or altogether.

13. The moving forces which act upon bodies, and the degrees of velocity communicated to them in a certain time, are proportional to the quantities of matter moved and the velocities communicated jointly; for, by the last proposition, when the velocity communicated in a certain time is the same, the moving force is as the quantity of matter moved. Thus, if a ball of ten pounds weight is made to move at the rate of 10 feet in a second, and another of one pound is made to move at the same rate, the moving forces will be in proportion to the quantities of matter; that is, as 10 to 1. Hence we may easily perceive, that when the quantity of matter is given, the moving force will be as the velocity. Thus, if two balls of ten pounds each

each

each are caused to move, one with the velocity of ten feet in a second, and the other with a velocity of five feet in the same time, the forces will be as the velocities; that is, as 10 to 5, or as 2 to 1; and hence, when both the quantities of matter and velocities are different, the moving forces will be according to these jointly. Thus if a ball of ten pounds is moved with a velocity of ten feet in a second, and a ball of one pound moves with a velocity of five feet in a second, the moving forces will be as 10×10 or 100 is to 1×5 , or as 20 to 1.

Here our author takes occasion to deny that there is any such thing as a communication of motion by an instantaneous impulse or stroke, as has commonly been supposed. Every degree of motion, according to him, is the effect of acceleration. "The latter way (says he) viz. the communication by instantaneous impulse, can obtain only in bodies perfectly hard and inflexible, which exist not in nature; and even in the abstract consideration of these as well as of other cases in mechanics, when metaphysical possibilities instead of the natural state of bodies are attended to, difficulties arise hardly explicable by any method of reasoning; but it is certain, that when finite velocity is communicated to any natural body, the time in which it is communicated must be finite also; so that when the body acted upon begins to move from quiescence, it must, during the action of the force, possess all the intermediate degrees of velocity between 0 and the velocity ultimately communicated.

"To exemplify this further, let it be supposed that a soft and flexible ball of clay impinges against another of the same sort, in the direction of a line joining the centres of the balls. At the first instant of the impact, the body struck will begin to move, and will proceed with a velocity inferior to that of the impinging body, the velocity of which will continue to decrease, and that of the other body to increase, as long as the impinging force causes a change in the figure of the two bodies; that is, till they have both acquired a common velocity; at which instant all acceleration ceases if the bodies be perfectly non-elastic. If the bodies be of such a kind, as, after having received impression from any impact, possess a power of restoring their changed figure with a force equal to that of the impact, it is manifest, that whatever velocity was communicated during the change of figure, an equal quantity will be superadded, during the restoration of it. In this case, after the acceleration arising from the impact during the change of the figure of the bodies has ceased, the bodies having then acquired a common velocity, a new acceleration will begin, being caused by the elastic force of the balls, which, acting in a direction of the lines joining their centres, tends to separate them, accelerating the ball struck, and retarding the other.

"From these considerations it appears, that in whatever degree the hardness of perfectly elastic bodies may differ, the effects of their impact will be the same, the weights and velocities before the stroke being given. For the figures of the striking and of the other body continually change, till they have acquired a common velocity, which depends only on the velocity of bodies and their impact, and is determined by the rules for the collision of non-elastic bodies. Moreover, the restoration of the changed figures, how great

or how small soever may have been the change, must cause an addition of velocity in the ball struck equal to that received from the impact.

"It follows also, that the effect will be the same, whether the bodies be both perfectly elastic, or whether one of them be perfectly elastic and the other perfectly hard; every thing else being given for the figure of the elastic body must change until the bodies have obtained a common velocity, which depends on the weights and velocities before the stroke only; and will be the same as if the bodies were non-elastic: the restoration of the figure will in this, as well as in the former case, cause an increase of velocity in the ball struck, equal to that before communicated. Although no substance in nature possesses perfect elasticity, or is entirely destitute of it, yet there are several elastic and non-elastic bodies subject to experimental trials, wherein the laws relating to collision are found to agree with fact to a considerable degree of exactness."

14. The accelerating forces which communicate velocity to bodies are directly as the moving forces, and inversely as the quantity of matter moved; for since by prop. 11. the accelerating force is as the velocity generated in a given time; and by prop. 13. the moving force is as the quantity of matter and velocity generated in a given time, it follows, that the moving force is as the accelerating force and quantity of matter moved jointly: that is, the accelerating force is as the moving force directly, and the quantity of matter moved inversely. Thus, let a mass of matter, equal to four ounces, be impelled by a force equal to three ounces; then the force which accelerates the mass of four ounces will be three-fourths when the acceleration of gravity is 1; in other words, it will generate, in a given time, three-parts in four of the velocity which gravity generates during any given time.

15. In bodies impelled in a rectilinear direction by forces acting uniformly, the velocities generated are as the forces and times in which they act, conjointly. Thus, suppose a force equal to ten acting upon a ball of ten pounds, and another also equal to ten acting upon a ball of equal weight, the former for one second, and the latter for two; it is plain that the velocity generated in the latter will be double to that generated in the former. But if we suppose the latter ball to be acted upon by a force equal only to five, then will both the velocities be equal, though the latter should continue for two seconds and the former only for one. In all practical inquiries of this kind, however, it must be remarked, that a standard velocity is to be obtained from observing what degree of velocity is generated by the force of gravity during a given time; one second, for instance.

16. If a quiescent body be impelled by any constant force acting upon it for a given time, the space described will be to the space described in the same time by a body moving uniformly with the last acquired velocity, in the ratio of one to two. In order to understand this, we must suppose the time to be divided into such small parts that the acceleration during any one of them is imperceptible: then it is evident, that at the end of two moments, the impulse continuing the same, it will have gained double the velocity it did the first moment; and this

Motion of Bodies. is manifest from the phenomena of falling bodies, which having descended for one second, acquire then a velocity twice as great as that which they had during the first second. That this proposition may be true, however, it is necessary that the velocity of the impelling power should be *infinite* with respect to that which the body itself can acquire; for whenever the body moved comes to acquire a velocity in any degree proportional to that of the moving power, then that proportion must be deducted from the acceleration; and when both come to be equal, no farther acceleration can take place. With regard to falling bodies, indeed, as far as our observations can go, were it not for the resistance of the air, this acceleration would go forward till the body had acquired a velocity much superior to any that we can now communicate, either by that or any other method. In all artificial accelerations, however, the velocity of the body moved soon becomes equal to that of the moving power, and then the motion goes on uniformly, which otherwise would continually increase.

17. The spaces which bodies describe from rest, by the action of constant forces, are in a compound ratio of the velocities last acquired and the times of motion: For the spaces described by the last acquired velocities continued uniform, are as those velocities, and the times of motion jointly; and the spaces described by the accelerating forces acting constantly for equal respective times, are half the former spaces by prop. 16. This will perhaps appear more intelligible from the annexed figure; in which the motion of a body, by an accelerated force, is represented by a triangle; for supposing the body to begin its motion from the point A, and to be uniformly accelerated until it arrived at the point C, it is plain that the velocity acquired would then be properly represented by the triangle ABC; but if the acceleration was then to cease, the velocity, and consequently the space passed over, would be represented by the parallelogram BCFE, double the triangle ABC. But let us suppose the acceleration still to go on, as is represented in the triangle BDF; it is plain that the space passed over in every small moment of time will be composed of a parallelogram formed by the velocity last acquired, and a triangle formed by the acceleration during that moment, which is entirely in terms of the proposition, that the spaces are in a compound ratio of the velocities last acquired, and the times of motion.

18. Constant forces which accelerate bodies, cause them to describe, from rest, spaces which are as the forces and squares of the times wherein they act jointly. For the spaces described are as the velocities last acquired, and the times of motion. This will be evident, from an inspection of the former figure; for in the triangle BDF, let B 1 represent the time in which a body acquires a certain velocity; then when it has attained the length of 2, the space passed over will be represented by a small square, being that of the first moment, and of a triangle representing the additional force the second moment.

19. The constant forces which accelerate bodies from a state of rest, are in a direct duplicate ratio of the velocities generated, and in an inverse ratio of the spaces described. Hence the following corollary is deduced, viz. that the last acquired velocities are in a subduplicate ratio of the accelerating forces, and a subduplicate ratio of the spaces described jointly.

20. If bodies unequal in quantity of matter be impelled from rest through equal spaces, by the action of moving forces which are constant, these forces are in a duplicate ratio of the last acquired velocities, and the ratio of the quantity of matter jointly.

In his observations on this proposition, our author takes occasion to consider the theory of those who insist, contrary to the opinion of Sir Isaac Newton that the absolute force of bodies is compounded of the quantity of matter and *square* of the velocity, instead of the velocity itself. "In the experiments (says he) which have been made on the force of bodies, the loss of motion from resistance has been more attended to than the communication of it by acceleration; and the reason probably arose from a want of adequate methods of subjoining accelerating forces, velocities acquired, and quantities of matter moved, to experimental trials; whereas the impact of bodies on fluids which they penetrate, by affording convenient opportunity for observing the depths to which bodies sink before all motion is destroyed, regard being had to the velocities of impact, and the weight and form of the impinging body, has seemed a more eligible method, however imperfect, of investigating the principles of motion.—When a body descends for three seconds by the force of gravity, it acquires, by a force of acceleration, a velocity of 96½ feet in a second: also, if a body be projected perpendicularly upward, with a velocity of 96½ feet in a second, the whole velocity will be destroyed in three seconds; and in like manner, every other property demonstrated concerning accelerated motions is found to belong to retarded ones, provided we attend to the following circumstances: If in any proposition relating to accelerated motion, the force is constant, it follows, that when this is applied to retarded motion, the retardation must also be constant. Moreover, since in accelerated motions the spaces are eliminated from quiescence, so in retarded motions the bodies are supposed to move to quiescence; that is, till all motion is destroyed by retardation: in whatever concerns motions of this kind, therefore, we must consider the retarding force to be directly as the force of resistance, and inversely as the quantity of matter.

"In order to illustrate this subject, it is to be observed, that if a body projected with different initial velocities be retarded by any constant given force, the whole spaces which the body describes are in a duplicate ratio of the initial velocities, which follows from what has been already demonstrated; and conversely, since when bodies are impelled by an accelerating force through various spaces, if these spaces are always as the squares of the last acquired velocities, it follows that the force of acceleration is constant: so when a given body is projected with different velocities, and is retarded by a given force, if the whole spaces described be always in a duplicate ratio of the initial velocities, it is concluded, that the force of retardation

Motion of
Bodies.

is constant. It is from this argument inferred, that the force whereby blocks of wood, banks of earth, &c. resist the penetration of bodies impinging on them, is constant; for it is observed, that the depths to which military projectiles of a given magnitude and weight, striking against a body of this kind, enter its substance, are in a duplicate ratio of the initial velocities, which has been sufficiently proved by Mr Robins, who first ascertained the velocities of military projectiles, and applied his method, among other useful purposes, to the discovery of the retardation which bodies suffer by passing through resisting substances.

"The forces of resistance, which are opposed to the motion of bodies impinging on substances which they penetrate, being granted constant, the propositions concerning acceleration already demonstrated may be applied to explain the motion of bodies, which, having been projected with given initial velocities, are interrupted by such obstacles as blocks of wood, banks of earth, or others of a similar kind.—For example, it has been demonstrated, that bodies moving from rest by the acceleration of constant forces, describe spaces which are as the accelerating forces and squares of the times jointly. By applying this proposition to retarded motions, we shall have the whole spaces or depths to which bodies impinging on the substances penetrate, as the forces of retardation and squares of the times wherein the bodies move, jointly. Moreover, it has been demonstrated, that if different quantities of matter be impelled from rest through equal spaces, the moving forces will be in a ratio compounded of the duplicate ratio of the velocities last acquired, and the ratio of the quantities of matter moved. It is from hence inferred, that in retarded motions also, if different quantities of matter be projected against any of the substances above described, with different initial velocities, and the whole depths to which the bodies penetrate are equal, the forces whereby the bodies resist the progress of the impinging bodies will be in a duplicate ratio of the initial velocities of impact and the quantities of matter jointly.

"By this proposition we may examine some of the experiments concerning the force of moving bodies, and the conclusions deduced from them by Bernoulli, Leibnitz, Poleni, &c. against the measure of force delivered by Sir Isaac Newton, which he described in the following definitions:

"The quantity of motion is measured by the quantity of matter in a moving body and its velocity jointly.

"The moving forces whereby bodies tend towards centres of attraction are as the quantities of motion generated in a given time.

"It follows, then, from these definitions, that the moving forces, acting for a given time, will be proportional to the quantities of matter moved, and velocities generated, jointly: so that if the ratio of the moving forces be known, and we can find by experiment what velocities are generated in given bodies by the action of them for the same time; the quantities of motion generated in the bodies may be estimated according to Sir Isaac Newton's definition. Moreover, since it is allowed that the effects of a resisting force to destroy are the same as those of an equal force to generate motion in a given time; it follows,

Motion of
Bodies.

that if the ratio of two resisting forces be known, the quantities of matter in bodies which impinge on substances, and penetrate them, and the velocities destroyed in a given time, will give the ratio of the quantities of motion destroyed, according to Sir Isaac Newton's definition.

"In many of the experiments alluded to, which have been greatly varied and multiplied, the resisting forces were made equal, by causing spheres equal in magnitude to impinge on a given substance which they penetrated; and the spheres being of given densities, it was observed in experiments, that whenever the densities or weights of those equal spheres were in an inverse duplicate ratio of their velocities, the depths to which they penetrated would be equal. The conclusions were these: the quantities of matter displaced by the moving bodies were equal, the depths to which the equal spheres penetrated were the same. Moreover, the whole motions which had been communicated to the bodies were destroyed; that is, the whole motion of the impinging bodies must have been as the squares of the velocities into the quantities of matter. But it plainly appears, that this conclusion is not applicable to the Newtonian definition, according to which the moving force generates motion in bodies: and it follows by what has preceded, that the resisting force by which the motion of bodies is destroyed, is proportional to the quantities of motion generated or destroyed in a given time respectively; and consequently, to estimate the quantity of motion destroyed, the time wherein resisting forces act should be equal. If, therefore, the times wherein the bodies in the experiment describe the equal spaces can be proved different, this will plainly show that the quantities of motion destroyed cannot be inferred from the experiment, the different times of the bodies describing the depths to which they sink not being taken into the account: this will be easily proved, since from proposition 17. it appears, that the spaces described are universally as the velocities and spaces last described jointly; and from what has been said, the converse of this proposition when applied to retarded motions must also be true. The spaces therefore being given as in the experiment, the times will be inversely as the initial velocities; which velocities being unequal from the experiment, it follows that the times are unequal. This being the case, it is manifest that no conclusion can be drawn from these experiments concerning the quantity of motion destroyed, tending to prove any inconsistency between the Newtonian estimation of force and matter of fact.

"It is next to be shown, that the experiments are strictly consistent with the Newtonian measure, and with the theory in general.—It has already been proved, that in accelerated motions the spaces described are in a duplicate ratio of the velocities last acquired, and the quantities of matter moved, and an inverse ratio of the moving forces. This proposition being applied to retarded motions, it will follow, that the whole spaces or depths to which the impinging bodies sink, are in a duplicate ratio of the quantities of matter, and an inverse ratio of the resisting forces; whence also the depths to which the bodies penetrate must be equal when spheres of equal diameters are projected against a given substance, the weights being in an inverse duplicate

Motion of
Bodies.Motion of
Bodies.

duplicate ratio of the initial velocities, which we find entirely correspondent to experiment. It seems indeed rational to suppose, independent of all theory, that, in estimating the quantities of motion generated or destroyed by given moving or resisting forces, regard must be had to the times wherein the forces act; because moving forces, or those of resistance, may be equal, and may generate or destroy quantities of motion varying in any assignable degree. For it is manifest, that a small resistance, opposed to a moving body for a longer time, may destroy more motion than a greater force acting for a shorter time; which sufficiently shows, that the times wherein the moving and resisting forces act, must either be equal, or must be taken into the account in estimating the quantities of motion generated or destroyed.

21. The moving forces which communicate, and the forces of resistance which destroy, the motion of bodies in the same time, will be in a compound ratio of the quantities of matter in the moving bodies and velocities generated or destroyed.—This and the preceding propositions have been fully illustrated and confirmed by experiments. From them we deduce the following facts: 1. When musket-balls, equal in weight and magnitude, impinge on a block of wood with different velocities, the resisting force being constant, we shall have the whole spaces through which the balls move in the wood as the squares of the velocities. 2. If balls of equal diameters, but different weights, impinge against a block with the same velocity, we have the depths to which they penetrate the block as the weights. 3. If balls of the same kind of substance, that is, of the same density, but of different diameters, impinge against a given block of wood or the same bank of earth with equal velocities, the depths to which they penetrate will be directly as the diameters of the balls.

When the force of resistance is not uniform, the same principle obtains in degree, though the laws are then various; for greater bodies always suffer less by retardation than smaller ones of the same density, moving through the same resisting medium, and projected with a given initial velocity: because, though the force of resistance increases with the increase of the body's magnitude, yet the weight in most bodies increases in a greater proportion. Thus, in cannon-balls, and other solid bodies, though the resistance of the air increases as the square of the ball's diameter, yet the weight increases as the cube. Thus, if a ball two inches in diameter is projected from the mouth of a piece, it is resisted by the atmosphere four times less than one four inches in diameter; but the weight of the latter, being eight times greater, makes the resistance less upon the whole in the large ball than in the small one. It is otherwise when the weight does not increase in this manner; for then the smaller the body is, the less resistance it meets with, and the faster it goes. This is manifest from aerostatical experiments; for small air-balloons always outstrip the larger ones: and the same thing is observable in boats; for the smaller ones, if they have the same advantages in proportion to their bulk, will always sail faster than the larger ones.

22. If bodies, projected with the same velocity, be retarded by different constant forces, these forces will be in an inverse ratio of the whole spaces described by

the projected bodies, until all motion is destroyed.—For example, let a body be projected on an inclined plane, in a direction contrary to that in which gravity acts in the plane, and with a velocity of 144.467 inches in a second. Suppose the body then projected, ascending along the plane, to describe 216 inches before its motion is destroyed; let it be required to ascertain the retarding force which opposes its ascent, that is, the proportion of it to the force of gravity. If the body were projected perpendicularly upward, with the given velocity of 144.467 inches in a second, it would rise only to 27 inches, as follows in Prop. 19. And since it ascends along the plane 216 inches, the retarding force on the plane will be to that of gravity as 27 to 216, or as 1 to 8; which is also the proportion of the height of the plane to the length of it.

From this proposition, having given the depth to which a body impinging against another penetrates it, the proportion of the retarding force of gravity may be determined. For example, Mr Robins found that a leaden ball of $\frac{3}{4}$ of an inch, or $\frac{1}{8}$ of a foot in diameter, impinging on a block of elm with a velocity of 1700 feet in a second, penetrated it to the depth of five inches, or $\frac{1}{4}$ of a foot; wherefore, since a body projected upwards with a velocity of 1700 feet in a second, would rise, if the atmosphere made no resistance, to the height of 44922 feet, we have the force by which elm retards the ball to the force of gravity as 44922 to $\frac{1}{4}$; or as 107,813 to 1.

On this theory it may further be observed, that the resistances opposed to spherical bodies, which impinge on a block of wood, a bank of earth, &c. depend not only on the tenacity or density of the parts, of which the penetrated substances are composed, but upon the diameters of the impinging spheres: so that, although the resisting and retarding forces be determined in any substance for a single case; yet when the diameters and weights of the impinging bodies vary, the forces of resistance and retardation opposed to the impact on the same substance will be different. By the preceding proposition, however, we may be enabled, from a single experiment made on the retardation of any substance opposed to a sphere, the weight and diameter of which are known, to infer the retardation in any other case, however the weights and diameters may vary.

23. If spheres of different diameters and different specific gravities impinge perpendicularly on fixed obstacles, the resisting forces of which are constant, but of different quantities, the forces which retard the progress of the impinging spheres will be in a direct ratio of the absolute forces of resistance, and the joint inverse ratio of the diameters and specific gravities of the spheres. No absolute conclusion can be drawn from this proposition concerning any matter of fact, unless an experiment be first made on the retarding and resisting force of some substance which is to be considered as a standard.

24. The whole spaces or depths to which spheres, impinging on different resisting substances, penetrate, are in the ratio compounded of the duplicate ratio of the velocities of impact, the joint ratios of the diameters and specific gravities of the spheres, and an inverse ratio of the absolute forces whereby the substances resist the progress of the spheres.

Motion of
Bodies.

Mr Atwood concludes this section with some problems relative chiefly to military projectiles; and in his next section (the 4th) considers the rectilinear motion of bodies acted upon by forces which vary in some ratio of the distances from a fixed point. This section chiefly relates to the powers of gravity and projection, by which the celestial bodies are actuated, and which consequently chiefly regards astronomy and the motion of pendulums; though there are likewise some curious particulars relating to the action of compressed air, the vibration of musical strings, and the undulation of fluids. The fifth section considers the motion of bodies immersed in fluids; but the sixth treats of a subject which properly belongs to mechanics, viz. the communication of motion to bodies revolving round an axis.

69
Of rotatory
motion.

In treating this subject Mr Atwood observes, that in the former part of his work he had supposed the accelerating, as well as resisting, forces, to act upon the body in a straight line passing through the centre of gravity of the moving; in which case every particle of the body must partake of the same degree of velocity, being equal to that with which the common centre of gravity moves. "But (says he) it frequently happens, that a body, or system of bodies, is so constituted, that when any force is impressed upon it, no motion can be produced except round a fixed axis; so that the velocity of the particles which compose the system will be greater or less according as these particles are farther from the common axis or nearer it. These circumstances should be attended to, in order to ascertain the motion of revolving bodies; the preceding principles of acceleration being not wholly of themselves sufficient for that purpose.

"In this investigation two things must be attended to. 1. The moving force by which the revolving motion is generated; and, 2. The inertia of the parts of which the system is composed. The moving force exerted on any given particle of the system, as well as its inertia, depends on its distance from the axis of motion, every thing else being the same; and if both these be ascertained, the absolute acceleration of the particle will be determined, and consequently the absolute velocity generated in a certain time. The methods therefore of determining these forces in any given circumstance should next be described.

"Let AFGH (fig. 112.) represent the circumference of a wheel which turns in its own plane round an horizontal axis, passing through its centre; and let a weight P, fixed at the extremity of a line AP, communicate motion to the wheel. Moreover, let the whole weight of the wheel be Q; and suppose this weight to be collected uniformly into the circumference AFGH; then, during the descent of the weight P, each point of the circumference must move with a velocity equal to that with which P descends; and consequently, since the moving force is the weight P, and the mass moved P+Q, the force which accelerates P in its descent will, by Prop. 14. be that part of the accelerating force of gravity which is expressed by the

fraction $\frac{P}{P+Q}$. The velocity, therefore, which is generated in P in any given time, is found from the rules before demonstrated. Thus, supposing Q to be

Motion of
Bodies.

equal to P, then will $\frac{P}{P+Q} = \frac{1}{2}$; and the weight P will be accelerated by a power which is to that of gravity as 1 to 2; and since gravity generates in bodies which descend for one second of time near the earth's surface a velocity of 32½ feet in a second; it follows, that the weight P will in the same time have acquired a velocity of 16½ feet in a second only.

"The parts of the weight Q which are uniformly disposed over the circumference AFGH, balance each other round the common centre of gravity S; their weight therefore is of no effect in accelerating or retarding the descent of P: and this will be the case whenever the axis of motion passes through the common centre of gravity. But in order to render the properties of rotatory motions more obvious, it will be convenient to dispose the parts of the revolving system so that the axis of motion shall not necessarily pass through the common centre of gravity: thus, instead of having the weight Q uniformly disposed over the circumference AFGH, let it be collected into any point Q. Here it is manifest, that if the mass Q be acted upon by gravity, the force which communicates motion to the system round S will be variable, it being the greatest when SQ is horizontal, and gradually diminishing till Q has arrived at its lowest point. But as we should begin with the most simple cases, the moving force must be constant. This will be effected by supposing the mass which is collected in Q to be destitute of weight, and to possess inertia only. It follows therefore, that during the revolution of Q round S as an axis, the moving force will be constantly equal to P, and the mass moved = P+Q. Consequently the force which accelerates the descending weight, or any point in the circumference, will be that part of gravity which is expressed by the fraction $\frac{P}{P+Q}$ as before.

"In these cases, the force which communicates motion to the system has been supposed a weight or body acted upon by the earth's gravity, and consequently constitutes a part of the mass moved, at the same time that it acts as a moving force: but motion may be communicated by a force which shall add nothing to the inertia of the matter moved: and it will be convenient in many demonstrations to assume the force of this kind; and in this case we have not to take the inertia into the account. Thus if any number of bodies without gravity collected into the points F, H, Q, (fig. 112.) are caused to revolve round the axis S, by a moving force P, the force which accelerates these bodies in their revolution will be $\frac{P}{F+H+Q}$; provided the bodies F, H, Q, be disposed at a distance from the axis of motion equal to the radius of the circle AFGH, at the circumference of which the moving force P is applied.

"In the preceding example, F, H, Q, &c. have been supposed to move with the same velocity; but when bodies revolve at unequal distances from the axis, their velocities of motion being different, other rules will be necessary to determine the force whereby any given point of the system is accelerated. In demonstrating the properties of rotatory motion, the revolving

Motion of Bodies. A moving system may be supposed to consist of one or more of the bodies A, B, C: the magnitude of these may be supposed evanescent; because, were the contrary supposition adopted, the particles in each body would be impelled by different moving forces, and exert different degrees of inertia in opposition to the communication of motion. But the force which impels each individual particle, and the effects of its inertia in different circumstances, must be known before the acceleration of the whole system can be determined.

"The bodies A, B, and C, which may be termed, according to the ideas just described, material points, are imagined to be connected together by some perfectly rigid substance, so as always to possess the same situation in respect to each other: and consequently no motion can be produced in any of them, excepting that all revolve at the same time round the common axis of motion.

"All the points in this imaginary subfiance, by which the parts of the system are connected together, partake of the same angular motion, describing circles round the common axis S. A force P therefore being applied to any point in the plane of its motion, and in the direction of any line in that plane which passes not through the axis, will communicate an equal angular motion to the whole. Thus let B (fig. 115.) represent a material point moveable about an axis of motion passing through S. With the radius SD describe a circle DGH. Now if B be connected with every point in the area of this circle, which is an inflexible subfiance, no force can be applied to move the circle but what must communicate the same angular motion to B. Let the force be applied at the point D; it is manifest, that in order to render its effects constant, the inclination of its direction to SD must be always the same, and in a given plane; and the most obvious method of effecting this, either in considering the subject theoretically, or in the practical illustration of it, is by applying a thin and flexible line GHDP round the circumference of the circle DGH, and stretching this line by a given moving force P. Here it is plain, that in whatever part the point D is situated, the effects of the force P will be the same as if it were directly applied to D in the direction of the plane of motion, and perpendicular to SD, and the point B will revolve with the same absolute and angular velocity in both cases.

Let now ABC (fig. 114.) be a fyflem of bodies of evanefcent magnitude and without gravity, moveable about an axis of motion which paffes through S it muft be obferved, that the imaginary fubftance by which the parts of the fyflem ABC are connected, muft contribute nothing either by its weight or inertia to accelerate or retard the motion of the material points A, B, C, which are caufed to revolve by the action of the given and conflant force P, applied at the diftance from the axis SD. The abfolute force of P to move D, or any point of the circumference, will be P; but the communication of motion to this point D is refifted by the inertia of the bodies A, B, C; which being moved with different velocities, and acted on by different moving forces, their inertia will not be eliminated by their quantities of matter only, according to the laws obferved in rectilinear motion; the force

which accelerates D , therefore, cannot be obtained by dividing P by $A+B+C$; but if an equivalent mass, or a quantity of matter, can be assigned, which being collected into any points of the circumference a, b, c , will cause an inertia or resistance to the motion of D equal to that exerted by the particles A, B, C , when revolving at their respective distances, the force which accelerates the circumference or any point in it D will be determined. Thus, let the mass Q , when collected into a , be such as will be equivalent in its inertia to A , when revolving at the distance SA ; also let R be the mass collected into b , which is equivalent to B when revolving at the distance SD ; and let T , the mass collected into C , be equivalent to C when revolving at the distance SC ; then will the mass moved by the force P be $Q+R+T$; and the force which accelerates the circumference $= \frac{P}{Q+R+T}$, being equal to

that by which the circumference or any point in it is accelerated when the point consists of A and B and C, revolving at the respective distances from the axis of motion SA, SB, SC."

Our author now proceeds particularly to investigate the motion of revolving bodies in almost all possible circumstances, deducing from his propositions many conclusions very useful in practical mechanics. Many of these regard the pendulum, and are therefore taken notice of under that article; others more immediately relate to the parts of mechanics particularly treated of in this article: the principal of which follow.

1. The force which accelerates the centre of gravity of a sphere, while it rolls down an inclined plane, is to the force by which it would be accelerated were it to slide in the ratio of five to seven. As our limits will not admit of inferring at length the demonstration of this and other propositions, we shall in this only observe, that when a wheel or a sphere *roll*, the circumference goes backward, while the centre moves forward; which retrograde motion must of necessity make the other slower than it would otherwise be: and this retardation Mr Atwood has determined to be in the proportion above-mentioned.

From this proposition the following corollaries are deduced. 1. The absolute force whereby motion is generated in the circumference of a sphere in such a situation, is expressed by a fraction consisting of twice the weight of the sphere divided by seven, and multiplied into another fraction consisting of the height of the plane divided by its length; that is, suppose the weight of the sphere to be represented by w , the height of the plane by h , and its length by l , the force by which the circumference of the sphere is impelled will be represented by $\frac{ew}{7} \times \frac{h}{l}$. 2. In the same man-

ner, let a cylinder roll down an inclined plane, keeping the axis always horizontal, and the force which accelerates the axis will be represented by the fraction $\frac{2}{3} \times \frac{h}{l}$.

2. Let AB (fig. 115.) represent a straight lever moveable round an horizontal axis of motion, which passes through S . Let the arms be SB, SA . Suppose a weight W to be affixed to the extremity of the

Motion of
Bodies.

70
Of revol-
ving bo-
dies,

Motion of
Bodies.

shorter arm, and to be raised by the weight P applied at the extremity of the longer arm, when the lever is horizontal. Required to determine the time in which W will be raised through any given height, the weight and inertia of the lever itself not being considered.

"When there is an equilibrium (says Mr Atwood) on any mechanic power, the proportion of the weight sustained to the power sustaining it, will, in all cases, be assigned from having given the dimensions of the mechanic power. An equilibrium having been once formed, the smallest addition of weight will cause the body to which it is applied on either side to preponderate. In this case a certain degree of motion is generated; and since the uses of the mechanic powers are not only to sustain forces in equilibrium, but to raise weights and overcome resistances, it is a problem of principal consequence to assign the absolute quantity of motion generated by a known moving force in given circumstances." The general solution of the problem is as follows:

"Let AB be the lever, W the weight moved by the power P; each acting in a direction perpendicular to the horizon. Let G be the common centre of gravity of the whole system, including the weights P and W with the lever itself; and o the centre of oscillation*, when AB vibrates round the axis S; the force which accelerates B when the lever is horizontal

$$= \frac{SG \times SB}{SO} = \frac{SB}{SO} \quad (c). \quad \text{If this be put } = F, \text{ the time}$$

wherein P descends through a perpendicular space x , and consequently wherein W ascends through the corresponding space; then $x \times \frac{SA}{SB} = \frac{\sqrt{x}}{F} \times \frac{1+x^2}{SB^2 \cdot 2.5}$

$$\&c. = \frac{\sqrt{x}}{T} \times \frac{SO}{SB} \times \frac{1}{1 + \frac{x^2}{SB^2 \cdot 2.5}}, \&c.$$

3. Let ABC (fig. 116.) represent a wheel and axle, its weight w , and let the axis be horizontal; having a given weight Q applied to the circumference of the axle, and P applied to the circumference of the wheel in order to raise Q. Required to assign the space described by the elevated weight Q in any given time. The solution of this problem, without attending to the demonstration, is this. Having found the accelerating power, which here is

$$\frac{P \times SD - Q \times SA \times SA}{w \times SR^2 \cdot (e) + P \times SD^2 + Q \times SA^2}$$

All this he puts $= F$; and then l being = 193 inches as before, the space described by Q in any number of seconds will be = the square of that number of seconds multiplied into F . On this proposition our author makes the following observations.

"Whenever motion is communicated to a body, a certain resistance must have been overcome by the moving force. This resistance is of various kinds. 1. The inertia of the mass moved, whereby it endeavours to persevere in its state of quiescence, or of uniform motion in a right line. 2. That of a weight or other

absolute force opposed to the action of the moving power. 3. Obstacles upon which the moving body impinging is retarded in its progress: such, for example, is the resistance which arises from the particles of a fluid thro' which a body moves. The estimation of these resistances, and their effects in retarding the motion of bodies acted on by a given force, are deducible from the laws of motion, and constitute a part of the solution of almost all problems relating to the motion of bodies.

"The moving forces also are of various kinds, viz. The power of gravity, muscular power, the impact of bodies, solid and fluid, &c. It has been shown, that the effects of these moving forces which are exerted on bodies in order to create motion, exclusive of the resistance opposed to them, depend on the various circumstances of the time in which they act, and on the spaces through which the bodies moved are impelled, &c.

"These considerations are urged, to show, that from the great variety of undetermined conditions which may enter into mechanical problems, there must of course be various methods of producing the same mechanical effect: and it is a very material part of the art, considered either in a theoretical or practical view, to proportion the means to the end, and to effect this with all the advantages which the nature of the case is capable of. It is the due observation of these particulars which contributes to render mechanic instruments complete, and the neglect of them defective, in their construction. This proper choice of means to produce mechanical effects, is frequently the result of long continued experience independent of all theory; the knowledge of which, however, when applied to practice, would save the artist much time and trouble, as well as would be productive of other advantages, which experience alone must be destitute of."

4. ABC (fig. 116.) is a wheel and axis moveable round an horizontal axis, which passes through S. Suppose a given weight Q, which is applied to the circumference of the axle; let it be required to assign the proportion of the radii of the wheel and axle, so that the time in which the weight Q ascends through any given space shall be the least possible. In this case, supposing the radius of the wheel to be 10 inches, and its weight 20 ounces; let the radius of the axle SA = 1 inch, the weight to be raised thro' any given space to be 100 ounces, the moving force by which it is raised to be 33 ounces; then the distance of the centre of gyration from the axis is $\sqrt{50}$ inches; and the length of the radius sought is 9.55 inches.—If, instead of raising the weight perpendicularly, it be required to draw it horizontally, and to assign the distance SD, at which, if a given force P be applied, the time of describing a given space shall be the least, and the moment of g the greatest possible, we have the following conclusion. "Let the quantity of matter to be drawn along the plane be four times greater than that which is contained in the moving

(e) R is the centre of gyration of the wheel.

Motion of Bodies,
 ing force; the radius of the axle SA being given; in order that it may be impelled with the greatest velocity possible and with the greatest moment, the radius of the wheel should be double that of the axle when the inertia of the wheel is not considered.

5. Let ARCH (fig. 117.) be a system of bodies moveable round a vertical axis which passes through the common centre of gravity of the system. Suppose DEG to be a wheel, the axis of which is vertical, and coincident with that of the system; let motion be communicated by means of a line going round this wheel, the string DP being stretched by a given weight P; let it be required to assign the radius of the wheel EGD, so that the angular velocity communicated to the system may be the greatest possible. Here, supposing the moving force to be one-fourth of the weight of the system, it should be applied at a distance from the axis equal to twice the distance of the centre of gyration, in order to produce the greatest possible angular velocity in a given time.

"In order (says Mr Atwood) to increase the action of a moving force against a weight to be raised, or resistance to be overcome, a combination of two or more mechanic powers is frequently made use of. Let p (fig. 118.) be a power applied by means of a line to the vertical wheel C: suppose the circumference of the axle K to be in contact with the circumference of any other vertical wheel B; so that the circumference of the wheel B may always move equally fast with that of the axle which belongs to C; let also the axle of B communicate motion to a vertical wheel A, to the axle of which a weight q is suspended, so as to act in opposition to p ; moreover, let the ratio of $l m n$ to 1 be the sum of the ratios of the radius of each wheel to that of its axle: then, if $p l m n = q$, the two weights p and q will sustain each other in equilibrium; but if $p l m n$ be at all greater than q , the equilibrium will be destroyed;" and our author gives a method of calculating the quantity of motion communicated in certain circumstances.

Our author next goes through a set of similar propositions relating to the pulley and wedge; after which he treats of the accumulation of power in ponderous cylinders, and the use of balast-wheels in machines, of which mention has already been made; and having diffused these subjects, he next comes to treat of the action of a stream of water upon a wheel revolving round an horizontal axis.

6. Let ABC (fig. 119.) represent a water-wheel which revolves round an horizontal fixed axis, passing through its centre S. Suppose DEF to be the axle of this wheel, and that a weight W is affixed to a line DW, so wound round the axle, that while the wheel is driven round its own plane by the force of the water impinging at I, the weight W may be raised in a vertical line; having given the area of the boards II, against which the stream impinges perpendicularly, and the altitude from which the water descends, it is required to assign the greatest velocity with which the wheel can revolve.

"When a stream of any fluid (says he) impinges perpendicularly against a plain and quiescent surface, the exact quantity of the moving force is equal to the weight of a column of the fluid, the base of which is the area upon which the fluid impinges, and the alti-

tude that from which a body must descend freely from rest by gravity, in order to acquire that velocity. This will be the moving force which impels the body when quiescent or just beginning to move: but after it has acquired some motion, the impulsive force of the body will be diminished; being the same as if the body were quiescent, and the water impinged upon it with the difference of the former velocities. Wherefore the altitude of the column of the fluid, which is equal to its impelling force, will be always as the difference between the velocity of the impact and that of the body itself; and since the altitudes from which bodies fall from rest are in a duplicate ratio of the velocities acquired, it follows, that the force of the impact will be in a duplicate ratio of the difference between the velocity of the wheel and that of the impact." The following is the conclusion drawn by Mr Atwood concerning the velocity: Putting A for the weight of the column of water when the wheel is quiescent; V the velocity with which it impinges on the boards II, &c. and y the velocity of the circumference sought; W

the weight of the wheel; then $y = V - V \times \frac{\sqrt{W} \cdot SD}{A \times ST}$.

7. Every other thing remaining the same, let the weight W be varied; and let it be required to assign the weight W, so that when the wheel has acquired its uniform velocity, the moment of W may be the greatest possible. Here the weight = $\frac{4 \times A \times SI}{9SD}$.

8. Having given a weight W to be raised by the action of the stream of water, the force of which is = A against a quiescent surface; let it be required to assign what must be the proportion between the radius of the wheel and that of the axle; so that the uniform velocity of the ascending weight may be the greatest possible. Here the length of the radius = $\frac{9W \times SD}{4A}$. Hence he concludes, that if the velocity with which the water impinges against the boards be doubled, the greatest moment communicated to a weight ascending uniformly, will be increased in the proportion of 8 to 1.

"The force (says Mr Atwood) which communicates motion to water-wheels, and the resistances which are occasioned by friction, tenacity, and various other causes, render the application of the theory of mechanics to practice, in these cases, extremely difficult. It is probably from this reason, that the construction of machines moved by the force of water, &c. has been almost wholly practical, the best improvements having been deduced from continued observation of the results produced in given circumstances; whereby the gradual correction of error, and varied experience of what is most effectual, have supplied the place of a more perfect investigation from the laws of motion.

"This seems to be the best method, as far as regards the practical construction of these machines, the nature of the case will admit of; for although there may be two ways leading ultimately to the same truths, i. e. a direct investigation from the laws of motion and long continued observation, independent of theory, the latter is frequently the most easy and intelligible, although less direct and less scientific; the former being inaccessible to those who possess the elementary

Motion of Bodies.

78

Atwood's observations on water-mills.

Motion of
Bodies.

mentary parts of mechanics only. It is in vain to attempt the application of the theory of mechanics to the motion of bodies, except every cause which can sensibly influence the moving power and the resistance to motion be taken into account: if any of these be omitted, error and inconsistency in the conclusions deduced must be the consequence. It was at one time supposed, from this inadequate application of the theory, that the same laws of motion would not extend to all branches of mechanics, but that different principles were to be accommodated to different kinds of motion. If this were truly the case, the science of mechanics would fall short of that superior excellence and extent which it is generally allowed to possess. For it is probable, that there is no kind of motion but what may be referred to three easy and obvious propositions, the truth of which it is impossible to doubt: and if we are not enabled to investigate the effects from the data in all cases, the deficiency must not be imputed to the science of mechanics, but to the want of methods of applying mathematics to it.

"This may be illustrated by an example, in order to show that the motion communicated to water-wheels, however complicated the data may be, is equally referable to the laws of motion, with the effects of the most uncompounded force. If a stream of water falls perpendicularly on a plain surface, the moving force arising from the impact only is equal to the weight of a column of water, the base of which is the surface upon which the water impinges, and altitude that through which a body must fall to acquire the velocity of impact. If the inclination of the stream to the surface should be changed, the force exerted in a direction perpendicular to the plane will be diminished in a duplicate ratio of the radius to the sine of inclination; the surface on which the water impinges remaining. Now, when the water falls on the boards of a water-wheel, the direction of the stream makes different angles with the planes of those boards; for since the particles of water descend in curve lines, they will strike any plain surface in the direction of a tangent to the curve on the point of impact. Moreover, the water will strike the higher boards TT with less velocity, and in a direction more inclined to their planes, than the lower ones II; it is also to be considered, that the stream will impinge on the boards at different distances from the axis of motion: all which circumstances must be taken into account, to find the force which tends to communicate motion to the wheel when quiescent; and when motion has been communicated, the force of the stream to turn the wheel will be determined in the manner already mentioned. But this is not the only consideration which affects the moving force: The force hitherto considered has been supposed to proceed from the impact of the particles only; in which case, each particle after it has struck the board is imagined to be of no other effect in communicating motion: but this is not wholly the case; for after the particle has impinged on the board, it will continue some time to operate by its weight; and this time will be longer or shorter according to the different constructions of the wheel. In the overshoot wheel, the continuance of the pressure, arising from the weight of the water, will be longer than in the undershot,

Fig. 119.

Motion of
Bodies.

the force which arises from the impact of the water being nearly the same in each case. The whole moving force, therefore, will consist of the impact determinable as above, and of the weight of the water descending along with the circumference, and communicating additional motion to it: this entire moving force being determined either by theory or experience, may be denoted by A. After the moving force which impels the circumference has been determined, the resistance to this force must be found; for on the proportion between the moving force and the resistance, the acceleration of the machine will depend. This resistance is of various kinds: 1. That of inertia. 2. If the machine is of that kind which raises weights, such for instance as water; the weight raised, allowing for its mechanical effect on the point of which we desire to know the acceleration, must be subtracted from the moving force before found; and this will be a constant quantity. There are other resistances all homogeneous to weight, viz. those of friction and tenacity, &c. which are variable in some ratio of the machine's velocity: and in order to proceed with the investigation, the exact quantity of weight which the friction is equal to, when the wheel moves with a given velocity, must be considered, as well as the variation of the resistances in respect to the velocities; which circumstances must be determined by experiment. If the force equivalent to the friction, &c. be subtracted from the moving force, the remainder will give the moving power, by which the circumference is impelled upon the whole: this being divided by the inertia of the mass moved, will give the force which accelerates the circumference.

The following apparatus has been invented by Mr Atwood, for illustrating his doctrines concerning accelerated motion, and has been found to answer the purpose more completely than any other we have heard of; discovering at once the quantity of matter moved, the force which moves it, the space described from rest, the time of description, and the velocity acquired.

1. *Of the mass moved.*—In order to observe the effects of the moving force, which is the object of any experiment, the interference of all other forces should be prevented: the quantity of matter moved, therefore, considering it before any impelling force has been applied, should be without weight; for although it be impossible to abstract the natural gravity or weight from any substance whatever, yet the weight may be so counteracted as to be of no sensible effect in experiments. Thus in the instrument constructed to illustrate this subject experimentally, A, B, fig. 120, represent two equal weights affixed to the extremities of a very fine and flexible silk line; this line is stretched over a wheel or fixed pulley *abcd*, moveable round an horizontal axis: the two weights A, B, being precisely equal and acting against each other, remain in equilibrium; and when the least weight is superadded to either (setting aside the effects of friction), it will preponderate. When AB are set in motion by the action of any weight *m*, the sum $A+B+m$ would constitute the whole mass moved, but for the inertia of the materials which must necessarily be used in the communication of motion: these materials consist of,

1. The

72
His apparatus
for experiments
on motion.

1. The wheel *abcd*, over which the line sustaining A and B passes. 2. The four friction wheels on which the axle of the wheel *abcd* rests: the use of these wheels is to prevent the loss of motion, which would be occasioned by the friction of the axle if it revolved on an immovable surface. 3. The line by which the bodies A and B are connected, so as when set in motion to move with equal velocities. The weight and inertia of the line are too small to have sensible effect on the experiments; but the inertia of the other materials just mentioned constitute a considerable proportion of the mass moved, and must be taken into account. Since when A and B are put in motion, they must necessarily move with a velocity equal to that of the circumference of the wheel *abcd* to which the line is applied; it follows, that if the whole mass of the wheels were accumulated in this circumference, its inertia would be truly eliminated by the quantity of matter moved; but since the parts of the wheels move with different velocities, their effects in resisting the communication of motion to A and B by their inertia will be different; those parts which are furthest from the axis resisting more than those which revolve nearer in a duplicate proportion of those distances. If the figures of the wheels were regular, from knowing their weights and figures, the distances of their centres of gyration from their axes of motion would become known, and consequently an equivalent weight, which being accumulated uniformly in the circumference *abcd*, would exert an inertia equal to that of the wheels in their constructed form. But as the figures are wholly irregular, recourse must be had to experiment, to assign that equivalent quantity of matter, which being accumulated uniformly in the circumference of the wheel *abcd*, would resist the communication of motion to A in the same manner as the wheels.

In order to ascertain the inertia of the wheel *abcd*, with that of the friction wheels, the weights AB being removed, the following experiment was made.

A weight of 30 grains was affixed to a silk line (the weight of which was not so much as $\frac{1}{10}$ th of a grain, and consequently too inconsiderable to have sensible effect in the experiment); this line being wove round the wheel *abcd*, the weight 30 grains by descending from rest communicated motion to the wheel, and by many trials was observed to describe a space of about 38 $\frac{1}{2}$ inches in 3 seconds. From these data the equivalent mass or inertia of the wheels will be known from this rule:

Let a weight P (fig. 121.) be applied to communicate motion to a system of bodies by means of a very slender and flexible line going round the wheel SLDIM, through the centre of which the axis passes (G being the common centre of gravity, R the centre of gravity of the matter contained in this line, and O the centre of oscillation). Let this weight descend from rest through any convenient space *l* inches, and let the observed time of its descent be *t* seconds; then if *l* be the space through which bodies descend freely by gravity in one second, the equivalent weight sought = $\frac{W \times R \times SO}{SD^2} = \frac{P \times l^2}{t^2} \cdot P$.

Here we have $P = 30$ grains, $t = 3$ seconds, $l = 193$

$$\text{inches, } t = 38.5 \text{ inches; and } \frac{P \times l^2}{t^2} = \frac{30 \times 193^2}{38.5^2}$$

$$30 = 1323 \text{ grains, or } 23 \text{ ounces.}$$

This is the inertia equivalent to that of the wheel *abcd*, and the friction wheels together: for the rule extends to the elimination of the inertia of the mass contained in all the wheels.

The resistance to motion therefore arising from the wheel's inertia, will be the same as if they were absolutely removed, and a mass of 23 ounces were uniformly accumulated in the circumference of the wheel *abcd*. This being premised, let the boxes A and B be replaced, being suspended by the silk line over the wheel or pulley *abcd*, and balancing each other: suppose that any weight *m* be added to A so that it shall descend, the exact quantity of matter moved, during the descent of the weight A, will be ascertained, for the whole mass will be $A + B + m + 23 \text{ oz.}$

In order to avoid troublesome computations in adjusting the quantities of matter moved and the moving forces, some determinate weight of convenient magnitude may be assumed as a standard, to which all the others are referred. This standard weight in the subsequent experiments is $\frac{1}{2}$ of an ounce, and is represented by the letter *m*. The inertia of the wheels being therefore $= 23$ ounces, will be denoted by 11 *m*. A and B are two boxes constructed so as to contain different quantities of matter, according as the experiment may require them to be varied: the weight of each box, including the hook to which it is suspended, $= 1\frac{1}{2}$ oz. or according to the preceding estimation, the weight of each box will be denoted by 6 *m*; these boxes contain such weights as are represented by fig. 122. each of which weighs an ounce, so as to be equivalent to 4 *m*; other weights of $\frac{1}{2}$ oz. $= 2m$, $\frac{1}{4}$ $= m$, and aliquot parts of *m*, such as $\frac{1}{8}m$, $\frac{1}{16}m$, may be also included in the boxes, according to the conditions of the different experiments hereafter described.

If $4\frac{1}{2}$ oz. or 19 *m*, be included in either box, this with the weight of the box itself will be 25 *m*; so that when the weights A and B, each being 25 *m*, are balanced in the manner above represented, their whole mass will be 50 *m*, which being added to the inertia of the wheels 11 *m*, the sum will be 61 *m*. Moreover, three circular weights, such as that which is represented at fig. 123. are constructed; each of which $= \frac{1}{2}$ oz. or *m*; if one of these be added to A and one to B, the whole mass will now become 63 *m*, perfectly in equilibrio, and moveable by the least weight added to either (setting aside the effects of friction), in the same manner precisely as if the same weight or force were applied to communicate motion to the mass 63 *m*, existing in free space and without gravity.

2. The moving Force. Since the natural weight or gravity of any given substance is constant, and the exact quantity of it easily estimated, it will be convenient here to apply a weight to the mass A as a moving force: thus, when the system consists of a mass $= 63m$, according to the preceding description, the whole being perfectly balanced, let a weight $\frac{1}{2}$ oz. or *m*, such as is represented in fig. 124. be applied on the mass A; this will communicate motion to the whole system: by adding a quantity of matter *m* to the former mass 63 *m*, the whole quantity of matter moved will now become

Motion of
Bodies.

become $64m$; and the moving force being $=m$, this will give the force which accelerates the descent of $A = \frac{m}{64m}$, or $\frac{1}{64}$ part of the accelerating force by which the bodies descend freely towards the earth's surface.

By the preceding construction, the moving force may be altered without altering the mafs moved; for fuppofe the three weights m , two of which are placed on A , and one on B to be removed, then will A balance B . If the weights $3m$ be all placed on A , the moving force will now become $3m$, and the mafs moved $64m$ as before, and the force which accelerates the descent of $A = \frac{3m}{64m} = \frac{3}{64}$ parts of the force by which gravity accelerates bodies in their free descent to the furface.

Suppofe it were required to make the moving force $2m$, the mafs moved continuing the fame. In order to effect this, let the three weights, each of which $=m$, be removed; A and B will balance each other; and the whole mafs will be $61m$: let $\frac{1}{2}m$, fig. 124, be added to A , and $\frac{1}{2}m$ to B , the equilibrium will ftill be preferved, and the mafs moved will be $62m$; now let $2m$ be added to A , the moving force will be $2m$, and the mafs moved $64m$, as before; wherefore the force of acceleration $= \frac{1}{32}$ part of the acceleration of gravity. Thefe alterations in the moving force may be made with great eafe and convenience in the more obvious and elementary experiments, there being no neceffity for altering the contents of the boxes A and B : but the proportion and abfolute quantities of the moving force and mafs moved may be of any affigned magnitude, according to the conditions of the propofition to be illuftrated.

3. *Of the fpace defcribed.* The body A , fig. 120, descends in a vertical line; and a fcale about 64 inches in length graduated into inches and tenths of an inch is adjufted vertical, and fo placed that the defcending weight A may fall in the middle of a fquare ftage, fixed to receive it at the end of the defcent: the beginning of the defcent is eftimated from o on the fcale, when the bottom of the box A is on a level with o . The defcent of A is terminated when the bottom of the box ftrikes the ftage, which may be fixed at different diftances from the point o ; fo that by altering the pofition of the ftage, the fpace defcribed from quiefcence may be of any given magnitude lefs than 64 inches.

4. *The time of motion* is obferved by the beats of a pendulum, which vibrates feconds; and the experiments, intended to illuftrate the elementary propofitions, may be eafily fo contructed that the time of motion fhall be a whole number of feconds: the eftimation of the time, therefore, admits of confiderable exactnefs, provided the obferver takes care to let the bottom of the box A begin its defcent precifely at any beat of the pendulum; then the coincidence of the ftroke of the box againft the ftage, and the beat of the pendulum at the end of the time of motion, will fhew how nearly the experiment and the theory agree together. There might be various mechanical devices thought of for letting the weight A begin its defcent at the inftant of a beat of the pendulum W ; let the bottom of the box A , when at o on the fcale, reft on a flat rod, held in the hand horizontally, its

No 200.

Motion of
Bodies.

extremity being coincident with o , by attending to the beats of the pendulum; and with a little practice, the rod which fupports the box A may be removed at the moment the pendulum beats, fo that the defcent of A fhall commence at the fame inftant.

4. *Of the velocity acquired.* It remains only to defcribe in what manner the velocity acquired by the defcending weight A , at any given point of the fpace through which it has defcended, is made evident to the fenfes. The velocity of A 's defcent being continually accelerated will be the fame in no two points of the fpace defcribed. This is occafioned by the constant action of the moving force; and fince the velocity of A at any inftant is meafured by the fpace which would be defcribed by it, moving uniformly for a given time with the velocity it had acquired at that inftant, this meafure cannot be experimentally obtained, except by removing the force by which the defcending body's acceleration was caufed.

In order to fhew in what manner this is affected particularly, let us again fuppofe the boxes A and $B = 25m$ each, fo as together to be $= 50m$; this with the wheel's inertia $11m$ will make $61m$; now let m , fig. 122, be added to A , and an equal weight m to B , thefe bodies will balance each other, and the whole mafs will be $63m$. If a weight m be added to A , motion will be communicated, the moving force being m , and the mafs moved $64m$. In eftimating the moving force, the circular weight $= m$ was made ufe of as a moving force: but for the prefent purpofe of fhewing the velocity acquired, it will be convenient to ufe a flat rod, the weight of which is alfo $= m$. Let the bottom of the box A be placed on a level with o on the fcale, the whole mafs being as defcribed above $= 63m$, perfectly balanced in equilibrio. Now let the rod, the weight of which $= m$, be placed on the upper furface of A ; this body will defcend along the fcale precifely in the fame manner as when the moving force was applied in the form of a circular weight. Suppofe the mafs A , fig. 125, to have defcended by constant acceleration of force of m , for any given time, or through a given fpace: let a circular frame be fo affixed to the fcale, contiguous to which the weight defcends, that A may pafs centrally through it, and that this circular frame may intercept the rod m by which the body A has been accelerated from quiefcence. After the moving force m has been intercepted at the end of the given fpace or time, there will be no force operating on any part of the fyftem which can accelerate or retard its motion: this being the cafe, the weight A , the inftant after m has been removed, muft proceed uniformly with the velocity which it had acquired that inftant: in the fubfequent part of its defcent, the velocity being uniform will be meafured by fpace defcribed in any convenient number of feconds.

Other ufes of the inftrument. It is needlefs to defcribe particularly, but it may not be improper juft to mention the further ufes of this inftrument; fuch as the experimental eftimation of the velocities communicated by the impact of bodies elastic and nonelastic; the quantity of refiftance oppofed by fluids, as well as for various other purpofes. Thefe ufes we fhall not infift on; but the properties of retarded motion being a part of the prefent fubject, it may be neceffary to fhew

Motion of Bodies.

in what manner the motion of bodies resisted by constant forces are reduced to experiment by means of the instrument above described, with as great ease and precision as the properties of bodies uniformly accelerated. A single instance will be sufficient: Thus, suppose the mass contained in the weights A and B, fig. 125. and the wheels to be 61 *m*, when perfectly in equilibrio; let a circular weight *m* be applied to B, and let two long weights or rods, each = *m*, be applied to A, then will A descend by the action of the moving force *m*, the mass moved being 64 *m*: suppose that when it has descended any given space by constant acceleration, the two rods *m* are intercepted by the circular frame above described, while A is descending through it, the velocity acquired by that descent is known; and when the two rods are intercepted, the weight A will begin to move on with the velocity acquired, being now retarded by the constant force *m*; and since the mass moved is 62 *m*, it follows, that the force of retardation will be $\frac{1}{2}$ part of that force whereby gravity retards bodies thrown perpendicularly upwards. The weight A will therefore proceed along the graduated scale in its descent with an uniformly retarded motion, and the spaces described, times of motion, and velocities destroyed by the resisting force, will be subject to the same measures as in the examples of accelerated motion above described.

In the foregoing descriptions, two suppositions have been assumed, neither of which are mathematically true: but it may be easily shown that that are so in a physical sense; the errors occasioned by them in practice being insensible.

1. The force which communicates motion to the system has been assumed constant; which will be true only on a supposition that the line, at the extremities of which the weights A and B, fig. 120. are affixed, is without weight. In order to make it evident, that the line's weight and inertia are of no sensible effect,

let a case be referred to, wherein the body A descends through 48 inches from rest by the action of the moving force *m*, when the mass moved is 64 *m*; the time wherein A describes 48 inches is increased by the effects of the line's weight by no more than $\frac{1}{883}$ parts of a second; the time of descent being 3.9896 seconds, when the string's weight is not considered, and the time when the string's weight is taken into account = 4.0208 seconds; the difference between which is wholly insensible by observation.

2. The bodies have also been supposed to move in vacuo, whereas the air's resistance will have some effect in retarding their motion: but as the greatest velocity communicated in these experiments, cannot much exceed that of about 26 inches in a second (suppose the limit 26.2845), and the cylindrical boxes being about $\frac{1}{4}$ inches in diameter, the air's resistance can never increase the time of descent in so great a proportion as that of 240 : 241; its effects therefore will be insensible in experiment.

The effects of friction are almost wholly removed by the friction wheels; for when the surfaces are well polished and free from dust, &c. if the weights A and B be balanced in perfect equilibrio, and the whole mass consists of 63 *m*, according to the example already described, a weight of $\frac{1}{4}$ grains, or at most 2 grains, being added either to A or B, will communicate motion to the whole; which shows that the effects of friction will not be so great as a weight of $\frac{1}{4}$ or 2 grains. In some cases, however, especially in experiments relating to retarded motion, the effects of friction become sensible; but may be very readily and exactly removed by adding a small weight 1.5 or 2 grains to the descending body, taking that the weight added is such as is in the least degree smaller than that which is just sufficient to set the whole in motion, when A and B are equal and balance each other before the moving force is applied.

Motion of Bodies.

M E C

MECHOACAN, a province of Mexico, or New Spain, in America, bounded on the north by Panuco and Gaudalajara, on the east by Panuco and Mexico Proper, on the south by the Pacific Ocean, and on the west by Guadalaraja and the South Sea. The soil is exceedingly fertile; and the climate so wholesome, that the Spaniards imagine it to be possessed of some peculiarly restorative quality; for which reason the sick and infirm flock to it from all quarters. The commodities are sulphur, indigo, farfaparilla, safafaras, cacao, vanelloes, ambergrise, hides, wool, cotton, silk, sugar, the root mechoacan or white jalap, and silver. This province formed an independent kingdom at the time Mexico was reduced by Cortez. The sovereign had long been the inveterate enemy of the Mexicans, and was considered, next to the republic of Tlascala, as the most formidable barrier against the extension of the imperial frontier. However, he submitted to Cortez without striking a blow, being intimidated by the wonders he had performed with a handful of men; and thus Mechoacan became a province of the Spanish empire, and a valuable addition to Mexico.

Vol. X. Part II.

M E C

The country at that time was exceedingly populous, but the natives are now much thinned; and that rather by the luxury and effeminacy introduced by the Spaniards, than by their tyranny. The capital of the province is also called *Mechoacan* by the natives, but *Valladolid* by the Spaniards.

MECHOACAN, or *White Jalap*, in the materia medica, the root of an American species of convolvulus brought from Mechoacan, a province of Mexico, in thin slices like jalap, but larger, and of a whitish colour. It was first introduced into Europe about the year 1524, as a purgative universally safe, and capable of evacuating all morbid humours from the most remote parts of the body: but as soon as jalap became known, mechoacan gradually lost its reputation, which it has never since been able to retrieve. It is nevertheless by some still deemed an useful cathartic; it has very little smell or taste, and is not apt to offend the stomach; its operation is slow, but effectual and safe. Geoffroy affirms, that there is scarce any purgative accompanied with fewer inconveniences. It seems to differ from jalap only in being weaker; the

refins obtained from both have nearly the same qualities, but jalap yields five or six times as much as mechoacan; hence it is found necessary to exhibit the latter in six times the dose of the former to produce the same effects.

MECKLENBURG, a duchy of Germany, containing those of Schwerin and Güstrow, is bounded by Pomerania on the east, by part of the marquisate of Brandenburg and the duchy of Lüneburg on the south, the Baltic on the north, and Holstein and Saxe-Lauenburg on the west. Their greatest length is about 120 miles, and greatest breadth upwards of 60. With respect to the soil, much cannot be said in favour of it, as it consists in general, either of sand, or large and desolate heaths, interspersed with moors, woods, fens, and lakes. It yields very little wheat, and not a great deal of oats, rye, and barley; but breeds a considerable number of sheep and cattle, has plenty of fish, with stone-quarries, salt-springs, alum, iron, and some copper. The principal rivers here are the Elbe and Stör, which fall into the Elbe as it glides along the borders of this country to the south-west; the Reckenitz, which discharges itself into the Baltic; as do the Peene, the Warnow, and the Stopenitz. This country has only one harbour on the Baltic, namely that of Rostock. In both duchies, exclusive of Rostock, are 45 great and small cities, with three convents, and a great number of manors and farms, belonging either to the duke, the nobility, or convents. The peasants are in a state of villinage; but the nobility enjoy very considerable privileges. The states are composed of the nobility and towns; and the diets, which are summoned annually, are held alternately at Sternberg and Malchin. The duchy of Schwerin appoints four provincial counsellors, and that of Güstrow as many; who rank according to seniority with the duke's actual privy-counsellors, as their marshals do with the colonels. The lesser committee represents the whole body of the nobility and commons, by whom the members are chosen freely and without controul, and no edict relative to the whole country can be published without their consent, or in prejudice of their rights. The inhabitants of this country are mostly Lutherans, under their superintendants. There are also some Calvinists and Roman Catholics. Besides the grammar-schools in the towns, there is an university at Rostock. The commodities of the duchy are corn, flax, hemp, hops, wax, honey, cattle, butter, cheese, wool, and wood, a part of which is exported, but hardly any manufactures.

Of the house of Mecklenburg, there are two lines

still subsisting, viz. that of Schwerin and that of Strelitz. The latter commenced in duke Adolphus Frederick 11. younger brother of the duke of Schwerin, and grandfather of the present duke of Strelitz, Adolphus Frederick IV. who entered on the government in 1752, and whose family hath lately received a great additional lustre by his Britannic majesty's taking his second sister for his consort, and by her own great merit and noble deportment in that high station. Besides the duchy of Strelitz, to this duke belong the principality of Ratzeburg, with the lordship of Stargard, the ancient commanderies of Miro and Nemero, and a yearly pension of 9000 dollars out of the Boitzenburger toll. The title assumed by both the dukes is *duke of Mecklenburg, prince of Wenden, Schwerin, and Ratzeburg, count of Schwerin and the country of Rostock, and lord of Stargard*. By the agreement concluded at Wittstock in 1442, the elector of Brandenburg, on the extinction of the male-line of the dukes of Mecklenburg, is entitled to their whole succession. The duke of Schwerin has two votes both in the diet of the empire and that of the circle. The matricular assessment for the duchies of Schwerin and Güstrow is 40 horse and 67 foot, or 748 florins monthly, including what is paid by Sweden for Wismar, and the bailiwicks of Poll and Neukloster. To the chamber of Wetzlar, these two duchies pay each 243 rix-dollars, 43 kruitzen. For the government of Mecklenburg, the administration of justice, and the management of the revenue, there is the privy council of regency, the demesne-chamber, the high and provincial court of justice, to which appeals lie in most causes, both from the consistory and the inferior civil courts, and which are common to both the dukes. As to the revenues, those of the Schwerin line must be very considerable, those arising from the demesne-bailiwicks and regalia alone amounting to 300,000 rix-dollars per annum. There is a tax on land that produces no contemptible sum, and that called the *prince's tax* is fixed at 20,000 rix-dollars: besides all these, there are also free-gifts. The whole revenues of the Strelitz branch are estimated at 120,000 rix-dollars. Each of these princes maintains a body of troops.

MECONIUM, the excrement contained in the guts of an infant at its birth. If this matter is not soon purged off, it occasions gripes, &c. A tea-spoonful of true castor oil is an excellent purge in this case; but the first milk from the mother's breast is usually sufficient, if it flows in due time.

MECONIUM, in pharmacy, the extract of British poppies. It has all the virtues of foreign opium, but in a somewhat lower degree.

DIRECTIONS FOR PLACING THE PLATES OF VOL. X.

In all, 22 Plates.

E R R A T A.

Page 121. col. 1. line 30. For "*Lord Napier, Baron of Merchilton*," read "*John Napier, Baron*," &c. And for "*Lord Napier*," in different other places in the course of the article, read "*Baron Napier*." The same error has been fallen into by several former writers, when treating of the invention of Logarithms. *John*, above mentioned, the real author of that invention, was, according to the custom of Scotland in his time, called *The Baron of Merchilton*; *Baron* being an appellation then given to all the great landholders, but which did not confer or imply the title of *Lord*. The first *Lord Napier* was *Archibald*, eldest son of the illustrious inventor of the Logarithms.

- P. 309. col. 1. l. 8. For *paternat*, read *paternat*.
 413. col. 2. line 26. For *Goetic*, read *Goetic*.
